

# PROBLEMS OF THE SELF

AN ESSAY BASED ON THE SHAW LECTURES  
GIVEN IN THE UNIVERSITY OF EDINBURGH  
MARCH 1914

BY

JOHN LAIRD, M.A.

## PREFACE

THIS volume makes the attempt to consider a group of problems which offer an unceasing challenge to philosophers, and the catchword 'Psychology without a Soul' gives the best general indication of the type of problem discussed. The aim of the enquiry as a whole is to show why there must be a soul, and in what sense precisely this soul should be understood. A complete or final answer to such a question is, of course, unattainable until the day when all speculative problems have found their solution; but the labours of philosophers and psychologists in recent years have made it possible to appreciate most of the important questions at issue with a clearer understanding than at earlier times, and permit the hope that an enquiry which keeps both the earlier and the more recent literature constantly in mind, need not be altogether fruitless.

One of the principal difficulties of this investigation is that so much of the relevant literature consists either of merely negative arguments, or else of discussions which are undertaken from a somewhat different point of view. It is not enough to prove the absurdity of a 'Psychology *without* a Soul,'

even if the proof be conclusive. The still more important question is: 'What is Psychology *with* a Soul?' Most of us feel that the 'pure ego' is a barren fiction, and the 'empirical ego' a formless mass. We want a synthesis which is concrete and definite, so far as any metaphysical synthesis can be. And the concrete treatment of the question is often to be discovered by the way, especially in the arguments for the primacy of will or feeling, or in disquisitions on the unity and continuity of the self, on the subconscious, or on multiple personality. An adequate discussion, therefore, must cast its net somewhat widely, and sometimes may seem not to have a very direct bearing on the central problem. The sketch of the plan of the argument in this book, which is given on pp. 42-44, together with the introductory chapter, may lessen the difficulties of the reader in this respect.

It was my privilege, as holder of the Shaw Fellowship in the University of Edinburgh, to give a course of lectures there in March 1914, and this volume expresses the argument of these lectures in a fuller and, I hope, a more adequate way. I should like to thank my audience for the courteous attention they gave to the lectures, and, in particular, to thank my former teachers in that University for the encouragement they have given me, both at the time of the delivery of the lectures and upon so many other occasions. I owe them a debt which I cannot repay. By a happy fortune I am similarly indebted to my

teachers at Cambridge, and although an obligation of this kind cannot be specified in detail, and may appear but imperfectly in the result, the sense of it remains undiminished. Every man's work is stamped by the training he has received, and, without that, he can accomplish nothing.

In the preparation of this volume for the press, I have received very valuable assistance from my colleague, Mr. M. W. Robieson, from Mr. John Baillie, Edinburgh, and from Mr. A. J. Dorward, St. Andrews; and my grateful thanks are due them for this assistance.

JOHN LAIRD.

QUEEN'S UNIVERSITY,  
BELFANT.

# CONTENTS

## CHAPTER I

	PAGE
INTRODUCTORY . . . . .	1

Interest of the question (1); its importance for metaphysics (2-4); objections to the feasibility of the enquiry, and to the necessity for it, answered (4-7); terminology (7-8); statement of the principal theories of the nature of the self with a view to the discovery of the best plan of procedure (7-11); proof that it is necessary to begin with experiences (11-15).

## CHAPTER II

PSYCHOLOGY AND THE SELF . . . . .	16
-----------------------------------	----

Impossibility of defining psychology, negatively, by reference to the non-physical (16-18); the distinction between 'act' and 'object' explained in the instance of cognition (18-22); the sources of psychological evidence, and the nature of proof attainable through introspection (22-30); introspective analysis of cognition (30-31); transition to the tripartite division of mind, and discussion of (1) meaning of terms, (2) common characteristics of conscious elements, (3) logical principle of division (31-36); reply to objections (36-38); formula for the positive principle of the constitution of mind (at any moment) derived from the above (38-40); problem whether a 'soul' is *also* required (40-42); outline of plan of argument in this book (42-44); points to remember (44-45).

## CHAPTER III

THE SELF AND THE BODY . . . . .	46
---------------------------------	----

Point of view of discussion (46); necessity for considering the implications of the distinction between body and mind by direct analysis (46-47); discussion of the 'internal sense,' in its traditional meaning (47-52); its literal meaning defended (52-53); the objects of the 'internal sense,' on this interpretation, although *subjective* in a

special sense, agree with the objects of the other senses in being present to mind, but not parts of it (53-57); reasons why there is a peculiar difficulty in distinguishing experiences from the objects of the 'internal sense' shown in a discussion of feeling (including emotion and pleasure-pain), multiple personality, James's view of personal identity, and activity (57-76); the sense, if any, in which consciousness occupies position (75-77); reply to a fundamental objection (77-79); summary (79-80).

## CHAPTER IV

### THE SELF AS FEELING . . . . . 81

Plan of argument in Chapters V.-VIII. (81); the usual view that experiences of feeling or will have the primacy in the self (81-82); meaning of the term 'feeling' (82-83); discussion of the primacy of feeling as defended in the argument from origin (83-87); from the 'subjectively subjective' character of feeling (87-92); from 'interest' (92-93); from the significance of moods (93-94); Mr. Bradley's view (94-100).

## CHAPTER V

### THE SELF AS WILL . . . . . 101

Course of discussion in Chapters V. VII. (101); common sense belief in the primacy of will (101-102); 'will' may mean either volition or activity-experiences generally (102-103); plan of argument in this chapter as preliminary to its successors (103-104); introspective analysis and description of activity-experiences (104-110); discussion of views of Berkeley in this connection (110-113); and of Münsterberg (113-116); problem whether activity-experiences are causes, and Hume's arguments on this question (116-123); more precise enumeration of activity-experiences, and definition of will in the narrower sense (123-126).

## CHAPTER VI

### PSYCHICAL AND PURPOSIVE . . . . . 127

Purposive behaviour probably the best *criterion* of the existence of mind, but this no proof of the primacy of will (127-128); meaning of 'purpose,' 'end,' and 'teleology' (128-133); psychology and biology (133); the meaning of 'purpose' in biology (133-134); the inconclusiveness of the negative arguments in favour of neo-vitalism (134-138); insufficiency of the positive arguments owing to the fact that they rely upon an unduly strained analogy between 'purposive behaviour' and conscious purpose (138-144); meaning of 'teleology' in biology (144-149); fundamental distinction between psychical and organic categories (149-151).

# CONTENTS

xi

## CHAPTER VII

	PAGE
THE PRIMACY OF THE PRACTICAL REASON . . . . .	152

Relation of the Practical Reason to the Will (152-153); the phrase indicates certain *metaphysical* arguments (153); criticism of Kant's proof of the primacy of the Practical Reason in the *Critique of Practical Reason* (153-160); and of his arguments in the *Critique of Judgment* (160-165); criticism of Fichte's arguments (165-174); and of Schopenhauer's (174-188), and of Bergson's (188-189); summary of results of Chapters IV.-VII., denying the primacy of the will, and defending the analysis of Chapter II. (190).

## CHAPTER VIII

THE SELF AS KNOWER . . . . .	191
------------------------------	-----

Reasons for adopting a somewhat different plan of procedure in this chapter, and account of the scope of the chapter (191-193); summary of preceding argument, and of its presuppositions (193-195); the problem of the *content* of cognitive acts (195-198); is an introduction to the fundamental problem of this chapter (198-200); problem whether the direct analysis of an act of knowledge implies a knower other than the act (200-201); criticism of Lotze's arguments (201-206); self-consciousness and self cognition (206-210); criticism of Mr. Bertrand Russell's view (210-212).

## CHAPTER IX

THE UNITY AND CONTINUITY OF THE SELF . . . . .	213
--	-----

Importance of unity and continuity in the theory of self-hood, and justification of delay in discussing it (213-215); plan of this chapter (215); preliminary considerations concerning (1) the preponderance of cognition, conation, or feeling in personalities of different types, and (2) concerning the danger of exaggerating the unity and continuity of the self (215-217); cognitive unity (217-218); Kant's proof and further explanations (218-223); criticism of Mr. Joachim (223-229); limitations to cognitive unity (229-231); development (231-232); logical character of cognitive unity (232-235); limitations to cognitive unity further explained (235-237); unity and continuity of feeling (237-238); the sentiments (239-240); reason in feeling and the logic of the sentiments (240-242), the unity and continuity of conation (242-244); summary of argument (244-245); personal identity (245-247); and the body (247-248).

## CHAPTER X

HOW IS THIS UNITY POSSIBLE? . . . . .	249
---------------------------------------	-----

The problem of the conditions of retentiveness (249-250); the physiological theory (250-256); psychical dispositions (256-257);

and subconscientness (257-258); arguments in favour of the existence of subconscientness derived from unconscious cerebration, psycho-analysis, acquired dexterity, the summation of stimuli, sense perception, and stored knowledge, are intended to explain the fact of continuity (257-263); but are inconclusive (263-265); the direct arguments more convincing (265-267); the range of explanation in terms of subconscientness (267-268); the term applies to *acts* (268-269); possibility that the observable continuity of the self need not require any further explanation (269-271).

## CHAPTER XI

### MULTIPLE PERSONALITY . . . . . 272

This kind of evidence supplies an invaluable test of the truth of a theory of the self (272); general discussion of dissociation (1) in evanescent, and (2) in more permanent forms (272-277); division of the types of cases (277-278); consideration of the evidence for the dissociation of personality with special reference to memory and retentiveness, organic sensation, the unity of endeavour and of feeling, (278-289); the problem of estimating the evidence for dissociation *into* personalities considered (289-293); probabilities suggested by the Beauchamp case (293-297); discussion of the problem whether a plurality of personalities can co-exist in the same body (297-300); difficulties raised by multiple personality especially important in connection with the soul substance (300-301); concluding comparison with normal personality (301-303).

## CHAPTER XII

### DISCUSSIONS OF THE SELF AS SUBSTANCE IN MODERN PHILOSOPHY . . . . . 304

Necessity for considering certain historical theories on this question (304-305); great divergence of views (305-308); the *esprit* of Descartes and its implications (308-310); Locke's ambiguous position and the conflict between empiricism and rationalism (310-319); Locke's interpretation of spirit (319-321); and of personal identity (321-324); Hume on personal identity (324-326); and on substance (326-328); and on the permanent ego (328-331); Kant's argument concerning the paralogisms of Pure Reason (331-334); Hegel (335-336).

## CHAPTER XIII

### THE SOUL . . . . . 337

Relation of this chapter to its predecessors (337-338); definitions of substance following Descartes, and interpretation (338-339); a merely logical definition of substance impossible (339-341); substance implies the existent and not merely objectivity (339-343); imaginary

# CONTENTS

xiii

PAGE

substances (343-344); the existent is subjectively known through the senses, and is objectively the particular (344-346); this implies stuff or *ὕλη*, (346); which is further explained (346-348); the unity or identity of substance (348-349); examples showing the apparent arbitrariness of our standards of this unity (349-351); the difficulty of the margin (352-356); independent existence of substances and uselessness of transcendent explanation (356-357); application of the general doctrine of substance to organisms (357-358); and to the soul as the necessary unity of experiences (358-362); the soul pre-eminently a substance (362-365); objections (365-367); immortality (367-370).

INDEX . . . . . 371

## CHAPTER I

### INTRODUCTORY

It is a truism that no study is more perplexing and, at the same time, more interesting to a man than the study of mankind and, in the end, of himself. Even if the pressure of the day's business leaves the average man but little time for self-reflection, he is still intensely interested in the personality of others, and the most obstinate questionings which beset him concern his soul and theirs. Moreover, the great objects of human interest affect personality and are tinged with personality. It is unnecessary to prove this statement by referring to the drama, the novel, history, biography. The thing is too obvious to require comment, and it is enough to illustrate it by mentioning a curious fact. Even those who in general have no great fondness for the study of biography are more keenly interested in the personal history of the great writers in literature than in their works, or, at any rate, are interested in a degree out of all proportion to the intrinsic interest of the careers of those authors. How else is it possible to explain the mass of literature and the years of discussion devoted to the shadowy author of the *Odyssey*, or to the stray hints which are all that is known of the career of Shakespeare? Nor is the reason very far to seek. As Samuel Butler says, 'Every man's work, whether it be literature, or music, or pictures, or

architecture, or anything else, is always a portrait of himself, and the more he tries to conceal himself the more clearly will his character appear in spite of him.<sup>1</sup> That is the truth unless, perhaps, such sciences as mathematics or physics are excepted. It may be a rare thing for the artist to be more interesting than the whole body of his work, but his character and career usually excite more attention than those of any one of his creations, and thus it is that the self is central among the things which touch the spirit of man.

It does not follow, of course, that the majority of mankind are strongly attracted by the philosophical problems which cluster round the self. There are some minds to which any metaphysical discussion is stale and unprofitable. They may admit that philosophy began with wonder, but they marvel still more at the fact of its continuance. In the broad sense in which every man is a metaphysician he is occupied, probably, with the metaphysics of self to a greater degree than with any other philosophical problem. He would be less than human if he never asked himself, What is a man? What is the soul? What is this miracle of three, or thirty, or threescore years? Nor could he fail to ask such questions so long as either theology or religion continues. Religion *must* raise the question whence man is and whither he goes, and it does not require a professional philosopher to point out that there is but little sense in asking such a question unless there is some comprehension of what it is that has come and what is about to depart. But the sense in which every man is a metaphysician is, after all, a very shallow one. Every man dallies with metaphysical conjectures, but there are very few who try to think philosophical problems *out*, resolutely and to the end, and unless a man make this attempt he has not begun to be a philosopher.

<sup>1</sup> *The Way of all Flesh*, p. 62.

At the same time, if and so far as metaphysical problems are really felt and earnestly attacked, the problems of the self deserve to take precedence of all others. If the self is central in point of human interest, it is also central in point of metaphysical importance. Nearly every philosophical problem has some bearing on the self, and conversely the most distinctive of the problems of the self are among the widest and the most important in philosophy. Pluralism and monism, individuality and value, realism and idealism are each, in a very distinctive fashion, problems of the self. The relation of selves to the Absolute is the hardest problem of idealistic monism, for, on that theory, the self is the most obstinate of all appearances. The ultimate reality of selves has been the basis of idealistic pluralism from the days of Leibniz onwards. And it is needless to elaborate in the other cases. These are perennial problems, but it is also fair to claim that the problems of the self bear a peculiarly close relation to much that is most characteristic of contemporary philosophical discussion. The importance of volition and the relation of body to mind are certainly among these problems, and both have a direct and obvious connection with the self. There are others besides the pragmatists who stoutly contend that action, conation, will are the basis of reality, and cling to the belief that *ago, ergo sum* deserves to succeed the Cartesian *cogito*. Again the contemporary discussion of the problem of Body and Mind tends more and more to exalt the importance of the self. We hear less of the conservation of energy, and more of the growth of living energy: less of dynamics, and more of purpose: less of atoms, and more of cells: less of natural selection, and more of progressive creation. These arguments, indeed, may prove mistaken in the end, but their tenor, at all events, is significant. The tendency, a generation ago, was to explain the

self in terms of something else. The increasing tendency, nowadays, is to explain other things in terms of the self.

Briefly, then, if any metaphysical problems are interesting, those of the self are most likely to be so : if any are important, those of the self must be among them. And there can be no serious objection to the feasibility of discussing these problems. There are, of course, superficial objections to the discussion of any metaphysical problem whatever, but these objections have not deterred metaphysicians in the past, and will not deter them in the future. They are easily refuted, and, in any case, have no peculiar relevance to this enquiry. The objections which may be raised, *in limine*, to a specific discussion of the self hardly require detailed consideration, although they certainly deserve a passing mention.

It may be maintained that the self, as it were, shines by its own light, that every one knows what it is, and that instead of finding, or inventing, problems in it we should restrict ourselves to the task of showing how other things may be explained in terms of it. But has this argument ever been seriously held? On certain metaphysical theories, it is true, the self has been proclaimed the clue to the riddle of existence. It is a 'transparent unity,' and therefore we cannot see into it; we can only see through it. Certainly it would be the rashness of mere folly to deny that the self, when understood, may prove itself the master-key of philosophy. But, if it is so, it owes its position not to its simplicity, and not to the ease with which it will fit, but to the fact, already mentioned, that most philosophical problems reach their climax in it. There are no idealists who believe that the self is transparent to the casual observer. A veil of obscurity intervenes before it can show itself as transparent as it really is, and that is enough for a beginning. In any

case, no one can really believe that there are no problems of the self. The writers<sup>1</sup> who contend that the self *must* be ultimate (because it is so extremely paradoxical) and those who contend that it *cannot* be ultimate (for precisely the same reason) do not argue wholly at random, and it does not require a believer in the Hegelian dialectic to see that this is a case which demands enquiry.

Although the argument that a man must know himself better than anything else is frequently maintained by philosophers, neither Descartes, nor M. Bergson, nor any other exponents of it would conclude that discussion of the self does not involve problems. After all, the better a thing is known the more enigmatical it becomes. It gives rise, not to fewer, but to more intelligent questions. And why is it easier to understand the self than to understand other things? There is no reason why knowledge should know its like more easily, or better, than anything else. If, in point of fact, the surest knowledge is that of the self, the reason lies, not in the necessity of the case and not in the nature of knowledge, but in the superior interest of the psychical and the greater preoccupation with it. And this fact, after all, may be disputed. It is just as important for any one to know himself and his fellows as it is for him to know anything else. He is as dependent on society as he is on bread; he requires a knowledge of stocks and shares as well as of stocks and stones. But the science of psychology is in its infancy when compared with the physical sciences, and that, at least, is a fact very hard to reconcile with the other 'fact' that is presumed. For the rest, it is unnecessary to consider the futile statement that we must know what the self is, because we are selves. We have opportunities, that

<sup>1</sup> Cf., e.g., Dr. M. Taggart (*Studies in Hegelian Cosmology*) and Mr. Bradley (*Appearance and Reality*) respectively.

is all; and opportunities for knowledge are not knowledge.

Indeed, for every one who contends that the self is not a fit subject for study, since it contains no mystery and involves no problems, there are many who maintain that it is useless to study it because it is the most inexplicable mystery in the world. 'One may understand the Cosmos but never the Ego: the Self is more distant than any star.'<sup>1</sup> So Mr. Chesterton, and so, I do not doubt, many who agree with him, and many who do not. This extreme, however, is scarcely more likely to be true than the other. Mr. Chesterton himself does not scruple to maintain that while it is possible to understand causes and effects in our own persons it is never possible to understand them in a laboratory, and those who argue in his vein might easily bring forward plausible reasons for believing that the self is less mysterious than the multiplication table. There are problems of the Cosmos and special problems of the millions of Egos which, as Mr. Chesterton seems to forget, are included in it. And there are no *a priori* reasons which condemn in advance the attempt to solve such problems. Problems of the self are on the same footing, in this respect, as others in philosophy. A philosophy can never be judged by its fruits, and therefore it is unwise to raise the question what fruit it can be expected to bear. No philosophical discussion, except one of a very limited scope, can hope for finality or maturity. But if there is no season of harvest in philosophy, there is at least the possibility of perpetual growth. A philosopher is like an explorer. He never knows his luck. If there is something to be discovered, after all *he* may find it. If he fails he may at least inform others that certain routes are impracticable or require better equipment. There is need for the venture

<sup>1</sup> G. K. Chesterton, *Orthodoxy*.

and there is room for hope. That is all that need be said.

For purposes of clearness it is necessary to make an explanation with regard to terminology. Generally speaking, the words 'person,' 'soul' or 'mind' may be regarded as synonyms for the self, and it would be mere pedantry to avoid using them as synonymous, unless there is some special liability to ambiguity in the particular context in which they are employed. Indeed, the words 'consciousness' and 'mentality' might sometimes be used in a similar sense, although with some inappropriateness and, in the latter case, with a wilful disregard of euphony. It is well to remember, however, that these terms are only approximately synonymous with the word 'self.' The two latter are abstract rather than concrete, if strictly employed, and, even if they are employed loosely, they may still imply a conception of the content of the self which might well be disputed. They imply that the self is nothing but consciousness, and this, whether true or not, is very far from being universally admitted. 'Person,' 'soul' and 'mind' come nearer to the meaning of 'self,' but each of them has a shade of significance which it is desirable to avoid at the outset of an enquiry like the present. The 'soul' and the 'self' may mean the same thing, but the latter is humbler and less steeped in extraneous associations; and, consequently, it ought to be used by any one who desires an *unaccented* reading of the problem. The word 'soul' seems too aristocratic to have its ancestry scrutinised or its income assessed. It breathes the rarefied atmosphere of poetry and theology. It leads, perforce and at once, to questions of vitalism, and the meaning of the indiscerptible substance. I am far from wishing to assert that the self is not a noble thing, but when we speak of the soul we are apt to forget that it may also be ignoble, and, what is worse, occasionally dull. Nor do I believe

that the problems of the spiritual substance and the vital principle are irrelevant to a discussion of the nature of the self. On the contrary, I intend to discuss them. The question is one of emphasis, and that emphasis may be all-important. A discussion of the soul makes it necessary to proceed at once to these questions. A discussion of the self need not approach them until after a more prolonged and more careful survey. Similarly, the term 'self' is broader and freer, though not looser, than either 'person' or 'mind.' 'Mind,' in common parlance, refers almost exclusively to the intellect, and, although the intellect is a part of the self, it is but a part, in the end, and possibly not the most important part. 'Person,' again, lays special emphasis upon certain ethical and legal implications (*e.g.* upon the degree of memory implied in the continuance of responsibility), and, although these characteristics certainly deserve consideration, it is desirable to avoid a terminology which brings them into unduly high relief. The word 'self,' then, includes what these other words include, and is preferable because it does not dictate the road which the discussion must follow.

It would clearly be futile to begin to discuss problems of the self without making a preliminary attempt to define what is meant by that term. The sage remark that a definition is the culmination rather than the starting-point of an enquiry is very properly disregarded even by those who make it. A preliminary definition is only an indication of the route to be followed, and therefore it is indispensable. The chief difficulty, in this as in so many other cases, is to find a definition which merely asks questions without begging them, and, probably, it is never possible to ask the right sort of question without begging or assuming something. Certainly, the self cannot be defined in such a way as to satisfy all parties, but it does not follow that there can be no consensus of

opinion as to the right line of enquiry into its nature. Different schools may agree in this, though their conclusions are as the poles asunder. Let us consider how that is possible.

The accounts of the self which are found in the works of different philosophers are very various and frequently conflicting. In proof of this it is sufficient to cite a few instances. According to Hume, the self is a succession of impressions and ideas which, fleeting and perishing, are in a perpetual flux and movement. This view, variously amended but not transformed, has its adherents to-day, and is one of the current interpretations of the theory which Lange has described as 'Die Psychologie ohne Seele.' Others, again, who are by no means followers of Hume are in substantial agreement with him at least in one respect. According to Mr. Bradley, 'the Ego that pretends to be anything either before or beyond its concrete psychical filling is a gross fiction and mere monster, and for no purpose admissible.'<sup>1</sup> Such a statement is very far from implying the way of impressions and ideas, but it clearly expels any Arch-Ego or other intruder who is not an ordinary guest in the mind's presence-chamber, entering in the usual way. And it is irrelevant whether the 'monster' has the shape of a permanent impression, as it had for Hume, or whether it adopts some other form.

Many, however, would deny that the vehemence of Mr. Bradley's assertion gives it any claim to acceptance, and they would dispute it with at least equal vigour. It is true that Lotze<sup>2</sup> declares that when he calls the self a 'simple and indivisible substance,' he is speaking 'in all innocence,' and merely means to express the fact of its indivisible unity. Such a theory is indeed incompatible with Hume's, for Hume meant to imply that a self is only

<sup>1</sup> *Appearance and Reality*, p. 89.

<sup>2</sup> *Metaphysic*, English translation, vol. ii. p. 173.

indivisible because it is divided. But it is not necessarily incompatible with Mr. Bradley's. The fact remains, however, that many would agree with Lotze in a sense that is not so innocent. They would take him to mean, as he certainly said, that a unity of consciousness must have a 'centre,'<sup>1</sup> and, with or without warrant, they would take this 'centre' to imply something either beyond or before the concrete psychical filling. They would assert that knowing without a knower is a contradiction in terms. They would maintain that no single experience can be understood without the assumption of a self, and that the self must be more than any or all such experiences. This interpretation may be wrong, but it is prevalent, and, at least on the surface, it is not nonsense. It is in fact the usual view, whether or not it is capable, in the end, of withstanding logical criticism. I do not know precisely what Dr. McDougall<sup>2</sup> means by the 'non-mechanical teleological factor' which he finds requisite for life in general and the soul in particular, but I do know that, in the form in which he means it, neither Hume nor Mr. Bradley could possibly accept it. There is, in other words, a profound opposition between those who maintain that the self cannot exist except within or between experiences, and cannot have any other content, and those who maintain that it must also be something more, if, indeed, it does not lie wholly outside such experiences.

And there are many other views. The late Mr. F. W. H. Myers, in his *Human Personality*, defends the theory that the self which is known is but a fragment which, when supplemented by the subconscious and by other hitherto unexplored tracts of mind, will be seen to belong to an astonishing and supra-personal whole. The grounds for this theory

<sup>1</sup> *Appearance and Reality*, p. 169.  
<sup>2</sup> *Body and Mind*, p. 304.

are lacking, but its possibility is beyond dispute. Similarly there is the 'transmission theory' in its two forms. In the first of these forms the body is regarded as a sort of prism which breaks the white beams of the eternal soul into the variegated personality we are accustomed to consider ours. In the second form the body is regarded as an organ of concentration. Consciousness is really diffused. The body collects it, and so creates those fickle, partial, paradoxical unities which are the men who see before and after. Either theory magnifies the office of the body, and neither stands alone in doing so. In one of his *Essays in Radical Empiricism* Professor James remarks: 'So far as we are "persons," and contrasted and opposed to an "environment," movements in our body figure as our activities; *and I am unable to find any other activities that are ours in this strictly personal sense.*'<sup>1</sup> The plain implication, from which there is no evidence that James would have shrunk, is that the personal and individualised self is the body, and although this view is rarely held (at any rate upon psychological grounds), it cannot safely be neglected.

Moreover, there is the doctrine that the self consists of that in which interest is felt, a theory which seems to imply a peculiar view of the relations of *meum* and *tuum*. But the theories mentioned are enough to illustrate the great disparity between the different philosophical theories of the nature of the self, and in view of this disparity it might well appear hopeless to try to begin this enquiry in a way that all parties would recognise to be fair and just. The disparity of the conclusions, however, does not necessarily indicate that there is no common ground in the way the problem is attacked. In the theories which have been mentioned there are two main lines of cleavage,

<sup>1</sup> *Essays in Radical Empiricism*, p. 170 n. For justification of the interpretation see the whole note. Italics mine.

and the theories themselves are but variants within these lines. The first question is whether the Ego is anything more than its concrete psychical filling, the second the degree in which the body must be regarded as constitutive of the self. Let us take one of the arguments and consider its logical bearing. Dr. M'Dougall says that 'the facts of our conscious life, especially the fact of psychical individuality, the fact of the unity of consciousness correlated with the physical manifold of brain-processes, cannot be rendered intelligible without the postulation of some ground of unity other than the brain or material organism.'<sup>1</sup> This proof relies on a basis which is negative in two respects. It maintains that a study of psychical processes, such as that undertaken by psychology, cannot be completely intelligible without a reference to something beyond the observed facts of mind. Psychical facts and psychical acts cannot supply their own explanation: they require a complement. And the second part of the argument is that this complement cannot be the body. Therefore, there must be a soul. This proof may or may not be valid, but, at any rate, one of its implications is clear. Even if the self is something beyond its psychical filling, it is necessary to begin with that psychical filling, and this is common ground. If the argument is that the soul is needed to explain the accounts of mental processes which psychology affords, the first step in the proof must be that of considering whether or not the processes thus described can be regarded as self-explanatory. When it is maintained that the body is the self, or the permanent ground of the self, an alternative hypothesis to that of the soul is defended, and whether it can or cannot be defended is of course a matter for argument. The only argument which does not fit naturally into this scheme is the view of Professor James that the individualised

<sup>1</sup> *Body and Mind*, p. 356.

self is the body, and his argument depends upon Introspection only. In other words, it is nothing but a description of what mental processes are and appear to be.

The best way of describing this result is to say that any account of the nature of the self must begin with an analysis of experiences. By experiences I mean the subject-matter of psychology, acts of knowledge, and acts of will, passions, emotions, strivings. Experiences, as the Germans say, are *Erlebnisse*, bits of conscious life which must be lived through, if haply they are to be understood. There is no better word in English to express this meaning than the word 'experiences' in the plural. Indeed, it is unfortunate that English philosophy, especially in latter years, should have spoken so consistently of Experience in the singular, Experience with a capital E. But no other translation of the word *Erlebnisse*, whether 'states of consciousness,' 'mental processes,' or any other, is so adequate or so convenient, and therefore it is necessary to make the best of an indifferent case.

The statement that an adequate account of the nature of the self must begin with experiences is very far from implying that the self is nothing but a collection or bundle of experiences. It is in fact compatible with the belief that the self is something beyond and above them, of which they are not even parts but only consequences. The statement means only that the one argument which can possibly convince any one of the necessity for the belief in a self over and above its experiences is an argument which is able to show that the experiences could not be what they are unless they depended upon this self. Experiences, it may be maintained, unite in a self, and this unity requires something more than the experiences themselves in order to be intelligible. Or again, the experiences are fleeting and perishing, and require the

assumption of a permanent self to explain their regularity and their continuity. Or again, it is clear from the analysis of even a single experience, that it would be nothing without a self. 'An act of resolve, without a subject, is a contradiction in terms.' The advantage of beginning with experiences is that this starting-point is compatible with all the theories and does not presuppose any one of them. It is equally consistent with the view that these experiences, when thoroughly investigated and properly understood, *are* self-explanatory, that *together* they are the self, or that the self falls within them. The relation of the self to the body involves special problems, and will be discussed in Chapter III. Except for these special problems, there can be no serious objection to the choice of this starting-point.

The first task, therefore, and the object of the next chapter is to consider, as precisely as possible, what experiences are, and then to discuss their relation to, or their union in, the self. This is, in the first place, an enquiry into the subject-matter of psychology, but it leads further of necessity. The problem of the nature of selfhood is never a problem of the mere description, or analysis, of experiences. Taken at its lowest terms, it is the question of how these experiences conspire together to be a self. If the subject-matter of the self, in a way, is that of psychology, the problem of selfhood is by no means coextensive with psychological investigation. From one point of view the nature of the self is one particular psychological question. From another point of view it is something too fundamental to be considered by psychology at all.

For the present purpose, however, it is irrelevant whether this discussion is best described as metaphysical or psychological. Metaphysics has no subject-matter which the sciences have not or, at any rate, could not have. It is only an historical accident if there are still some realms of existence

which science has hitherto refused to explore, and has left as a sort of residuum to the metaphysician. Apart from such accidents metaphysics has the same subject-matter as the sciences, including psychology. The only difference is that metaphysics adopts a point of view which is wider than that of the sciences and, to put it paradoxically, more thorough and more searching. Further discussion is required in order to discover whether metaphysics must, or need not, re-interpret the results of science in order to secure their intelligibility or its own, and the sequel will consider whether it is necessary to abandon this relatively psychological standpoint, or whether it can be incorporated without substantial modification. A Japanese gymnast poises himself on an insubstantial pile of loose bricks, and then knocks them down in order to show how clever he is. A metaphysician, perhaps, does not require this Oriental dexterity.

## CHAPTER II

### PSYCHOLOGY AND THE SELF

THE definition of the subject-matter of psychology is not, unfortunately, free from controversy. Indeed, the very descriptions of this subject-matter may arouse dispute. It is frequently said, for instance, that psychology investigates states of mind, but such a phrase, obviously, is an open invitation to bickering. What is the relation of mind to its states? A state must be a state of something, as Locke's 'modes' had to be modes of something, and consequently the defenders of 'psychology without a soul' might reasonably contend that the paradoxical character of their conclusions is increased without any warrant by the purely verbal difficulties into which this description brings them. The phrase 'states of consciousness' is equally objectionable. If consciousness is, properly speaking, an abstract term, it ought to mean a characteristic belonging to each of a number of events. Psychologists are probably innocent of any deep designs in their preliminary definitions of their subject-matter, but innocence, like Nature, has consequences.

Let us begin by asking how the subject-matter of psychology differs from that of other sciences. This problem is too often attacked as if it were merely a question of distinguishing psychical from physical, and therefore it leads to the conclusion—a fatal one

if uncritically accepted—that whatever is not physical is psychical. The physical world, however, exists continuously throughout a uniform time in a homogeneous space of three dimensions. This, at least, is its current interpretation, and there may be, and are, many objects which are neither physical, in this sense, nor psychical. It is plain, for instance, that the direct objects of perception are not physical in precisely this way. No reflective man can be so utterly blind to the known differences between tactual and visual space, to the facts of optical illusion, to the differences arising from perspective and the blendings and contrast of colours, as to suppose that what he perceives, as he perceives it, is necessarily this stable, orderly, physical world. The presentations of sense may correspond to this world, roughly and in the main; they may even be distorted glimpses of it, but it is to the last degree improbable that the physical world itself, uninfluenced by the subject, is the direct and invariable object of sense-perception. And if, in any instance, it is not, then there is an instance of an object which is not, strictly speaking, physical. But, on the other hand, there is no reason for asserting that such objects are psychical or parts of mind. A dream table, for instance, is not part of the dreaming mind, any more than the table used in waking life is part of the mind of the percipient. These are objects for mind, not parts of mind. They may, indeed, be *subjective* objects—that is to say, the special characteristics of what is presented, the dream table or any other object, may depend, in part at least, upon the particular mental condition of the subject who perceives. But that is beside the point. To be partially dependent upon mind is not the same thing as to be part of mind. To argue in that way would be as futile as to maintain that because a steamer cannot move without coal it follows that the coal is part of its motion.

Or, again, consider certain judgments. Suppose, for instance, that we judge that similarity depends upon identity in the end, or that relations cannot subsist without terms. The objects of these judgments are not psychical. There is nothing specifically mental about similarity, or identity, or relation. On the contrary, they are universals, and each mind, and each act of each mind, is particular. But these universals are surely not physical. They may hold of particular physical objects existing in space, but they are not themselves spatial; and physical objects are. It is impossible, therefore, to define an experience, or any part of the self, by saying that it is that sort of existent object which is not physical. Such a definition would include, as part of the self, much that is not part of it at all.

It is necessary, therefore, to adopt some other mode of enquiry. Let us consider the previous instances again. In both cases, those of the percepts of sense and those of the universals which form the objects of certain judgments, there are two elements to consider, and these, though inseparable, are none the less distinct. The act of being aware of this or the other object, whether that object be perceived or intellectually apprehended, must be distinguished from the object itself. I may judge to-day that the diameter and circumference of a circle are incommensurable, and I may judge it to-morrow. The acts of judgment are distinct because they occur at different times, but the object in each case is one and the same. That particular relationship may be apprehended at any time, and the time at which it is apprehended is irrelevant to it. The distinction, in this instance, is particularly obvious. In other instances it is not so obvious, but it is, none the less, necessary and important. Acts of perception and judgments of the intellect necessarily refer to an object, and the latter are either true or false: they are never

identical with the object to which they refer, and there cannot be knowledge unless there is both act and object. The temporal reference, implied in this example, may seem only a special case. It is not really so. The act of knowledge is part and parcel of the stream of time: it is conditioned by what goes before, and leaves its mark on what succeeds, but the knowledge itself must be timelessly true, and error is timelessly false.

That is true even when the object of judgment is not a universal but a particular event in time. It is timelessly true that King George V. visited the Potteries in April of 1913. Time cannot impair the truth of that statement. It was true before the stars began: it will be true when the moon is no more. It will not, in all human probability, be always true that he is reigning now. But the reason is that the word 'now' is ambiguous, since it may refer to a variety of dates. Perhaps this obvious distinction is less manifest in the case of acts of perception than in that of acts of judgment. For the object of perception may be contemporaneous with the act, and exist only when and so far as the act exists. Let it be so. The distinction between the act and the object still holds. A cathedral, as it is presented to the mind, is grey and made of stone. The mind is neither coloured nor stony.

Simple as these considerations are, they still require some explanation, but the reader will probably comprehend the explanation more readily if he understands, in a general way, the conclusion to which this analysis points. We have been dealing with a special class of instances, those, namely, of cognition, and have found that in any cognition two elements must be distinguished—the act of awareness, and the object of that act. In many cases, so far as the argument has gone, there is no reason for supposing that the object itself is specifically mental. On the other hand, the act

of awareness is always mental, always an experience and a part of the self; and the subject-matter of that part of psychology which deals with cognition is just these acts and nothing more. The acts are conscious acts, they are experiences,<sup>1</sup> and their being is to refer to an object. Cognitive acts, therefore, as thus interpreted, are parts of the self. But it is necessary to offer some further explanations.

(1) To distinguish between an act of knowledge and the object known does not imply any divorce between knowing and being, nor does it imply that any act of knowledge is conceivable which does not refer to some object. On the contrary, the act has its being as a mode of reference to an object. If it did not so refer it would be nothing. None the less, the act must be distinguished from the object, since, to mention only one reason, different acts may refer to the same object. It is irrelevant whether any objects can exist towards which there is no such act of conscious reference. This analysis, by itself alone, supplies no reason for denying that they may. It is hardly a paradox to say that Neptune may have existed before any one, terrestrial or super-terrestrial, was aware of the fact. But such a possibility (or probability) does not affect the intimateness of the cognitive relation. When it exists it is as intimate as any relation can be. When it does not exist the question of intimacy does not arise.

(2) The use of the term 'object' also requires explanation. It is clear, of course, that the word

<sup>1</sup> In the previous chapter (p. 13) I used the German term *Erlebnisse* as if it were synonymous with 'experiences' in the sense of this essay. It should be noted, however, that the German usage is not quite uniform, since the word *Erlebnisse* sometimes implies the whole complex act and object, and this, of course, is very different from the narrower sense in which I am employing the term 'experiences.' I cannot understand how we can be said, in any strict use of language, to 'live through' anything except conscious acts, and therefore the extension of the term beyond such acts seems unjustifiable. The fact of usage must be noted, however. This point is mentioned by Dr. G. E. Moore in his paper on *The Status of Sense-data*, given to the Aristotelian Society in the meeting at Durham in July 1914.

'object' does not mean, simply and solely, a physical thing. A physical thing may be an object of cognition, but so are presentations of sense, and so are universals, and so are experiences when any one thinks of them. I have used the word 'object' in the sense which implies nothing but the complement of the act of reference, whatever a man is aware of in so far as he is aware of it. It may be objected, however, that this usage is very misleading. Is the 'object,' existentially, *merely* the complement of the act of reference, as those who believe in the ultimateness of the subject-object relation seem to maintain? Is it not more usual to think of an 'object' as something which may exist on its own account, and possess, perhaps, a wealth of qualities which most minds observe only in part, and some minds scarcely at all? If so, no one can suppose that subjective presentations are 'objects' in this sense.

I agree that there is a difference, and shall try to illustrate it by an example. One man may think of Henri IV. as a French monarch who flourished some centuries ago, a second may think of him as an apostate Huguenot, a third as the husband of La Reine Margot. We may suppose that such scattered pieces of information are all that John Roe or Richard Doe possesses, and that each of them has only one piece of information. In that case there is clearly a distinction between Henri IV. himself, the son of Jeanne d'Albret, many of whose qualities were known only by himself, while others cannot now be rescued from the débris of history, and, to put the matter popularly, the various 'ideas' of him in the mind of Mr. Doe or Mr. Roe. The former, to use a convenient distinction, may be called<sup>1</sup> the 'object,' the latter the 'material' of an act of reference. The 'material'

<sup>1</sup> For further explanation of the terms 'material' and 'quality' *vide*, e.g., HUNGERI, *Logische Untersuchungen*, Zweiter Teil, pp. 399 ff., and MESSER, *Empfindung und Denken*, pp. 50-53.

belongs to the object, each part of it is characteristic of Henri IV., but it need not exhaust his nature, and it is limited, not by Henri IV., but by the imperfect information of those who are thinking of him.

It is best, I think, to use 'object' in the widest possible sense, and to call the 'material' of a cognitive act an 'object,' instead of restricting that term to the narrower meaning I have indicated. The distinction, ultimate or not, is doubtless important in many cases, and those who will may remember it. But it has no peculiar importance in this connection, except in so far as it may resolve a possible ambiguity and misunderstanding in some minds. In either sense of the word there is a plain distinction between an act of knowledge, which is an act of reference, and that to which the reference is made. The psychologist is concerned primarily with the former, and not with the latter.

To proceed. The object of this chapter is to analyse the subject-matter of psychology in the hope of gaining some insight into the nature of the self. In other words, it attempts to explain the nature of experiences. Such 'explanation,' of course, does not imply that these experiences can be defined in terms of anything else. That would be absurd, for no one can know what an experience is like unless he has had it. It may, however, be possible to discover some property common to all experiences and belonging to nothing else, and it is advisable to try to make this discovery in order to know precisely where we stand. Hitherto only one class of experiences has been considered, *i.e.* acts of cognition, and these, certainly, are very far from being the whole furniture of the self. Still, they are parts of that furniture and, therefore, are important. Their being is to be a mode of reference to an object.

On what evidence was this result obtained? Clearly by direct analysis, that is to say, by introspection. And here we may pause to consider the

sources of evidence at our disposal. Any psychological enquiry (and this enquiry, up to the present, has been primarily psychological) has two sources of evidence, direct and indirect. The indirect evidence may be called interpretative. Languages, institutions and, for that matter, flint heads and ancient pottery indicate the existence, present or past, of certain kinds of experiences, and are interpreted on the strength of this belief. Direct evidence, however, in matters psychological can only be obtained by introspection, and that, it may appear, is very unsatisfactory. There are arguments which try to prove it impossible. It could hardly satisfy a court of law because it can never muster two independent witnesses. If a man can have introspective knowledge of his own experiences, he cannot have such knowledge of the experiences of any one else; and even if two men have similar experiences, who can verify the fact directly? As this question is of considerable importance, it will be well to consider it.

There are three questions to ask: (1) Is introspection possible? (2) If it is possible, is it really the only direct evidence attainable? and (3) Can it form the basis of a fruitful enquiry?

(1) A well-known objection to the possibility of introspection is that of Auguste Comte.<sup>1</sup> Briefly stated, his argument is that the activity of knowledge cannot turn round and catch itself. To this it is sometimes replied that introspection is really retrospection, and that conscious acts can be remembered although they cannot be observed. That is a view which seems contrary to experience: at any rate the act of introspection and its object seem so nearly contemporaneous that it is arbitrary to insist that in all cases there must be an interval of time between them. Moreover, in the vast majority of cases, that only is remembered which has been observed, and

<sup>1</sup> *Cours de philosophie positive*, i. 34 8.

introspection on this theory would be a startling and widespread exception to the general rule. The difficulty, however, is a manufactured one.<sup>1</sup> In the first place the Comtian argument could only hold of cognitions and not of other experiences. The cognitions of feelings, desires, and volitions would not be subject to the objection. For introspection is a species of cognition, and an act of cognition could not be said to catch itself if it were aware of a feeling or a desire. And the difficulty is manufactured even with respect to cognitions. Every act of cognition must refer to an object other than itself, and therefore no act of cognition can be aware of itself. But why cannot one act of cognition be aware of another act, and why, even, should not the two processes be contemporaneous? The act of cognition which is the object of the act of introspection will, it is true, refer to some other object. If we catch ourselves thinking, we catch ourselves thinking about something. But this is only a complication, not an objection. When the object of our introspection is an act of cognition the act will be a part of a complex including the object to which it refers. And why not?

(2) It may be questioned whether introspection is the only direct evidence of the nature and existence of psychical processes, but there is no doubt whatever that it is by far the most important evidence. The question at issue is the interesting and much-debated one of the possibility of a direct acquaintance with the experiences of other minds. The accepted theory, strongly opposed by believers in telepathy and others, is that any one self is acquainted with others by a process of inference only. It is interesting to note that the writers who oppose this view frequently base their case upon arguments which, to say the least, are fully consistent with its truth. Professor

<sup>1</sup> This is true, even omitting the important question of the sense in which cognition can be said to be an activity.

Alexander, for instance, writes as follows : ' We may press a yielding object and become aware of its soft firmness and have besides an experience of our own effort of grasping. But there is all the difference between this and the experience of a hand which in any degree returns the pressure of ours ; and that is why we so much dislike an unresponsive hand which seems to us inhuman and disappoints expectation.'<sup>1</sup> This, surely, is no argument for Professor Alexander's case. The whole point of the opposite contention is that a human hand really behaves differently from a wooden hand or a stuffed hand, and we feel that we can only explain the differences by supposing that the motions of a human hand are directed by a conscious self in the same way as we believe that the motions of our own hands are directed.

Strictly speaking, this is a side issue with reference to the main question we have in view, but its interest will excuse a slight delay. Let us consider the accepted position. Darby and Joan, in the evening of their days, know one another better than they know themselves, but this intimate acquaintance, according to the theory, is only a complicated inference. It seems direct and spontaneous for no other reason than the potency of habit. The child, too, comes to know that his brother or his nurse is, like himself, a conscious being through inference from their bodily actions and words. A little boy in the nursery knows that his brother is in a passion, because his brother's gestures and contortions are the same as he himself is wont to make when angry. But surely such a theory inverts the order of psychological development and implies a ridiculous degree of sophistication in the infant mind. The plain fact is that a man can recognise and construe the physical symptoms of expression far more accurately in the case of others than in his own, and there is no reason

<sup>1</sup> *Mind*, N.S. vol. xxii. No. 85, p. 18.

to believe that adults are different from children in this respect. The angry child seldom knows that he has clenched his little fist, still less does he know the aspect of his countenance. But he can easily perceive these facts in the case of others. Accordingly, it is monstrous to maintain that we infer the existence of consciousness in others from the similarity of their behaviour to our own.

A more adequate psychology of development would explain the facts in a different way. The child discovers that his nurse and his mother will respond to his wants in a way that inanimate objects will not respond, and therefore he comes very early to distinguish between human behaviour and other kinds of behaviour. This type of explanation is certainly consistent with the theory that there is no direct acquaintance with other minds. Through the senses and experience the child comes to distinguish between responsive and unresponsive beings, and when he comes to distinguish himself as himself he is able, by a gradual and unconscious logic, to believe without a question that responsive beings have a like nature to his own. And this theory is tenable. It is, of course, an expression in highly intellectual terms of a process of inference which is so obscure and involved that it should not, perhaps, be dignified by the name of inference. But, on the other hand, it is not the only tenable theory, and it may not be the most probable. Even granting the premises of the theory, there is no reason to believe that the child recognises his own selfhood *before* he recognises the selfhood of others, and unless the impossibility of a direct acquaintance with other minds is assumed from the outset, there are no grounds for asserting that there is a fundamental distinction between the logical and the chronological orders of discovery.

There is something repugnant to the ordinary mind in the doctrine that even those who are nearest

and dearest to him are known to him only as moving pieces of matter, although he can infer with a high degree of probability that they have thoughts and feelings like his own. Nearly any one would admit that it is easier to describe the actions and words of his fellows than any other part of their being and that it is usual to justify any assertion of their states of mind by referring to their behaviour. Indeed the doubters would be silent if they reflected that they know their own experiences better than the physical expression of them, while they can describe minutely, or at least recognise easily and readily, the expressive behaviour of others. It is easy to recognise the voice of a friend on the gramophone, but very easy to mistake one's own, and such examples could easily be multiplied. But the current philosophical theory is an illegitimate inference from this fact. Our direct acquaintance with other minds, if it exists, is too fragmentary and ambiguous to be the sure foundation of a theory, and no one should build upon it. But to deny it *in toto* is equally unjustifiable. Let us put the issue in another way. If knowledge begins with the senses, it is surely rash to maintain that the senses which acquaint us with matter are the only ones. That is begging the question. If there were direct acquaintance with other minds there would be an additional sense to those which are usually recognised. And, again, matter or physical objects are not the direct objects of the senses even if they are known through the senses, and therefore it is fair to argue that we may know our fellows as directly as we know physical things. That would not be a legitimate argument if the fact were that we *first* discovered them to be things, and subsequently inferred that they were things with minds. For that would be a double inference and, perhaps, neither step in it is mathematically certain. But there need not be two

steps in the argument, and I am convinced that the repugnance of common sense to the doctrine I am discussing is based upon an instinctive rejection of the doctrine that there are two steps. The sound of the human voice *means* a mind just as surely and just as directly as any complex of sensory presentations *means* a physical object, and errors in the case of the former are no more frequent than in that of the latter.

(3) At the same time it is necessary to admit the importance of the distinction between interpretative and introspective evidence. Introspection, if not the only, is the best and the surest direct evidence which can be obtained of the nature of experiences, and there is no sufficient ground for denying that it is good evidence. It is a sort of observation, akin to perception. Now it is a characteristic of any object which is observed that its distinguishing features cannot be adequately defined in terms of anything else, but can only be pointed out. Moreover, it can only be understood by those who have already observed something similar. Let us consider, for example, the distinguishing characteristics of redness. No one can understand what red means until he has seen something red. He may define its causal conditions and enumerate the rate of vibrations in the ether. But a blind man can understand these and yet he does not know the meaning of red. Thus if we rest our case on the results of introspection we can only point out these results and cannot prove its truth by direct observation of others. But that holds of all observation whatever, and where would science be without observation? It is no real objection that the objects of introspection are, in the sense already explained, subjective. Probably the presentations<sup>1</sup> of

<sup>1</sup> I have used the word 'presentation' both here and in other places, although I am well aware that there is no real agreement between psychologists as to its precise meaning. In a sense there is agreement. A 'presentation' is what Locke called an 'idea,' and it is used with an

sense-perception are equally subjective. And yet science continues. There may be no reason to suppose that two or ten men ever see the same thing. There is every reason to suppose that they have similar presentations and can thence infer the nature of the physical object which occasions the perceptions of both of them. In the same way there is every reason to suppose that the experiences of one mind are substantially similar to those of another and therefore that the results of introspection have much more than private significance.

There is an interesting passage in Locke's *Essay* which bears upon this point: 'What perception is every one will know better by reflecting on what he does himself when he sees, hears or thinks, than by any discourse of mine. Whoever reflects on what passes in his own mind cannot miss it. And if he

---

even more exclusive reference to sense perception than his 'ideas.' In the terminology of this chapter, a 'presentation' is the 'material' of any act of sensory apprehension, and I do not think there is any serious objection to the use of the term in this sense. The passage in the text does not require any further refinement of interpretation, however important that might be from some other point of view. It is necessary, however, to indicate briefly the nature of the controversies which cluster round the term.

Since a presentation is that which is directly presented, or given, to sense perception at any moment, it is clear that there will be disagreement about the precise meaning of the term if there is any difference of opinion concerning the nature of what is directly given. And there is a very marked disagreement upon this point. Mr. Bertrand Russell and Dr. G. E. Moore generally use the term *sense-data* in this connection, and Dr. Moore, still more recently, has adopted the term *sensibles*. The word, of course, does not matter, but the meaning attached to the word may matter a great deal. A *sense-datum*, or a *sensible*, is, as nearly as possible, synonymous with the *minimum sensibile* of Berkeley or Hume, and the natural interpretation of the writings of those who adopt this terminology is that the direct object of perception at any moment is a collection of *sensibles*. But, although all psychologists would agree that presentations are fragmentary, most of them would argue that they are relatively extensive, and most would certainly maintain that they cannot be rightly regarded as a collection of *minima sensibilia*. On the more usual view, a presentation is a more or less fragmentary part of a *continuum*, and is felt as such. The incompleteness of a presentation is part of its being. Some writers, indeed, go further and contend that every sense-presentation implies, in some way or other, a reference to a *thing*. Not only is it felt to be incomplete, but its completeness and its incompleteness are felt to be dependent on some more permanent condition, and the true analysis of what is *directly* given in sense must involve all these elements. I agree with this last view, but it would be irrelevant to pursue the subject further.

does not reflect, all the words in the world cannot make him have any notion of it.'<sup>1</sup> But Locke's discourse was more than a stimulus to reflection. It was an aid and a guide to it.

Accordingly, the direct evidence in the present connection depends principally upon introspection. Let us examine our experiences by introspection, and see whether they have any common and characteristic features. We began by considering cognition, and that element in the self requires still more careful examination. When that task is completed we must consider experiences other than cognitive.

What is called the 'quality' of an act of cognition must be carefully distinguished from its 'material' and its 'object,' and the meaning of this term is best described by reference to an earlier example. Let us suppose that our knowledge of Henri IV. is derived solely from reading Dumas's novel, *La Reine Margot*. In that case we should think of Henri as the husband of Margot, and the master of La Mole, as a bold yet cautious schemer, as the rescuer of Charles of Valois. We may judge that Henri was all these things. But we may also doubt it, or we may merely entertain the supposition without actually believing that the facts were thus. Novels, we know, are not history, and Dumas wrote scores of them. In such cases the acts of believing, doubting, judging, entertaining, are different psychical acts whose material is the same, viz. Henri IV. as portrayed in this novel of Dumas. They are all modes of cognition, but they are different modes, and it is to this difference that the term 'quality' is applied. It is unnecessary in this place to give a precise or exhaustive account of the various ways in which an act of cognition may differ in 'quality.' It is enough to indicate the nature of the term.

Every act of cognition, then, has its being as a

<sup>1</sup> *Essay*, Book II. chap. ix. § 2.

mode of reference to an object. But it is a mode of reference having a distinct quality, and the quality of the act can be discovered by introspection. As it is a distinctive experience, it cannot, however, be defined in terms of anything else, and therefore a great variety can be discovered in the analysis of those cognitive experiences which form so important a part of the self. There is a certain unity in our subject-matter, but there is also variety; and the unity and the variety minister to one another.

The analysis of cognition will furnish a clue to the investigation of the other main classes of experience which are parts of the self, and if we consider the connections of these other experiences with one another and with cognition, we shall have done something towards understanding the self, and something more than merely describing its parts in fictitious isolation. The subject-matter of psychology, so fundamental in a discussion of the nature of the self, has, since the time of Kant (and even before his time),<sup>1</sup> been distinguished into the three main divisions of cognition, feeling, and endeavour. This tripartite division has frequently been challenged, but the defence has proved itself stouter than the attack. Let us, then, accept it provisionally and consider what it means. There are three principal questions to ask: (1) What is the scope and meaning of the terms employed? (2) Is there any common characteristic of the three classes which are thus distinguished? If there is, and the division is exhaustive, we have reason to hope that this common characteristic will be the distinguishing mark of the psychical. (3) What is the principle of the division, its *fundamentum*, to use the old logical term, and how are the three classes related to one another?

(1) Cognition has already been considered, but we have not considered feeling or endeavour, and psycho-

<sup>1</sup> By Tetens and Mendelssohn.

logists are by no means agreed as to the exact sense in which these terms should be used. Feeling, for instance, is sometimes restricted to pleasure and pain, and at other times is applied to any vague massive experience, such as organic sensation or coenaesthesia. And the controversies with regard to endeavour, or activity, are endless. Is activity an experience, or is it not? Is it, or is it not, a 'psychological scandal'? We cannot avoid these controversies altogether, but to consider them fully would lead beyond the limits of a general survey. It will suffice to indicate the sense in which the terms are used in this essay. By feeling is meant the way in which the subject is affected by any object of which he is conscious. Generally, he is either attracted or repelled by it, and consequently all 'qualities' or modes of attraction or repulsion are qualities of feeling. Not only pleasure and pain, but the thrill of excitement of which Bain spoke, and the emotions of love and fear, anger and disgust, and the rest, should be classed under this head. So should desire and aversion, despite the fact that most psychologists call them modes of conation, that is to say, of endeavour. That there is a close connection between desire and conation is undoubted. There always is an intimate connection between feeling and endeavour, but desire and endeavour are, none the less, easily distinguishable. A man may desire very keenly to play a game of billiards after dinner, and his guest may desire it equally. All the endeavour that may be required of either is to walk to the table and begin.

By endeavour is meant a characteristic mode of conscious experience whose being is to seek an object. Striving, seeking, and the choice in volition, are among its modes or 'qualities.' I shall try, in a later chapter, to explain and defend this statement.

(2) The common characteristic of all three classes

in the tripartite division is that they are conscious experiences which are not primarily objects for consciousness, but modes of reference to an object. This statement agrees with the scholastic doctrine that the *differentia* of a state of consciousness is its 'intentional inexistence.' Its being is to intend or refer to an object. It *means* the existence of that object, and not its own. An act of consciousness may, indeed, be the object of another act, *i.e.* of an act of introspection. But that is irrelevant and accidental. The primary and fundamental characteristic of a conscious experience is its reference to an object, whether or no it is itself the object of a further act of reflection. This, I think, is the only common characteristic of that which is psychical, and it seems a meagre result of so much painful analysis. It does not tell us what experiences are, but only something about them. It gives no hint of the richness and variety of the self. That information can be given by introspection, and introspection only. But any enquiry of the present sort must be equally meagre. No analysis of the common characteristics of that which is psychical can hope to present a full picture of conscious life, and yet the result need not be altogether useless, just because it is meagre. It may show the plan and structure of a conscious self, and if it does so it is justified.

Indeed, a more plausible objection would be that the analysis is false. It holds of cognition, no doubt, but in what respects does it hold of the other divisions of consciousness? Cognition must be of something. But does seeking, or striving, always refer to an object? May there not be a blind striving? This alternative analysis, although plausible, must be rejected. Striving implies a prospective attitude, which may be vague, but must be present, and be part of the being of the process of striving. Volition clearly implies an object, for in all cases of volition we

choose to do *something*, and a similar account holds for any other species of endeavour. The mode of reference is different from that of cognition. But the reference itself is an essential constituent of the process of endeavour.

The case of feeling, however, is not so clear. Feeling, according to Hamilton, is 'subjectively subjective,' and that, being interpreted, means that feeling has no reference to an object, but is, simply and solely, a state of the subject. This position is certainly not unreasonable, and I shall try to consider it more carefully later, but the presumption is against it. It seems plain that the feelings of love, or hate, or desire imply reference to an object. They are ways in which the subject is consciously affected by an object, and to be affected in this way implies reference to the object. Indeed, the very instances of pleasure and pain on which Hamilton based his case lend themselves more naturally to an analysis which is precisely the reverse of his. Is it not true, as a general rule at least, that we are pleased *with* something, and pained *at* something? If that is usually the case there is a strong presumption that feeling, also, refers to an object, and is similar to other experiences in this respect.<sup>1</sup>

(3) What is the *fundamentum* of the tripartite division? If the division is logically sound it must have a principle, and that principle cannot be merely the difference between one class of experiences and another. The assent of judgment, for instance, is much more closely allied to the choice of volition than to the attitude of doubt. But doubt and judgment are instances of cognition, and choice pertains to endeavour. Indeed the three members of the tripartite division are so closely connected with one another, so indispensable to one another, that it is much harder to distinguish them than it is to

<sup>1</sup> For a fuller discussion see Chap. IV.

distinguish assent from mere supposition, or desire from aversion. The *fundamentum*, therefore, must be sought in a different direction.

If every experience is a mode of reference to an object, and if this characteristic is important, then it ought to be of use in helping us to distinguish the great classes of experiences. And examination shows that it does.

Cognition is a mode of reference to an object. It includes perception, doubting, believing, affirming, denying, and these have, at least, certain negative characteristics in common. They do not attempt to change their object, and they cannot occur simultaneously when there is reference to one and the same object. A man may doubt one part of the story which he hears, deny a second part, and believe in the rest, but he cannot both doubt and believe the same part of the same story at the same time. The first characteristic, however, is of more importance, and consideration of the second may be postponed. Cognition is *adynamic*. It seeks to know its object, not to change it. If it changed the object it would frustrate its own aim. For then it would know (or doubt, or deny), not that object, but something else. Cognition neither changes its object, nor is affected by it. It is, by its essence, impartial, unbiassed, disinterested. It is not an *impression*, but an *act*, and it is an act which is adynamic.

On the other hand, the two remaining members of the tripartite division are *dynamic*, though each in a different way. Feeling is the way in which the subject is consciously affected by the object. It is essentially passive. It expresses the action of the object on the subject. In this respect it is manifestly different from cognition, and endeavour is equally different. Endeavour is the conscious action or re-action of the subject towards the object. Its being is to affect the object, to change it or to sustain it

when, without endeavour, the object would disappear. This is the aim of volition and striving. The result of this analysis, therefore, is a division of experiences which meets all logical requirements, and is based upon a principle, or *fundamentum divisionis*, which is necessary and important. That is clearly true of the subdivision of the dynamic experiences. Dynamic influence must be either passive or active. It must express the way in which something is affected, or in which it affects something else, and we find, not by an *à priori* or arbitrary procedure, but by a direct interrogation of introspection, that there are experiences which fall within each class. The distinction between dynamic and adynamic may seem, indeed, to be on a different footing. Logically it must be exclusive and exhaustive, because it is a division by dichotomy; but divisions by dichotomy are often merely formal and yield no important information. In the present instance, however, that criticism is not pertinent. To describe cognition as adynamic may seem to be a mere negation, but is not really so. The description seizes on one of the most fundamental characteristics of cognition as it appears to introspection, and gives as much definite and positive information as any general description could; for it emphasises the most vital distinction between cognition and other experiences in a way which no other distinction does. It is hardly too much to say that this distinction, if clearly recognised at the outset, saves a world of barren controversy. For the proof, consider the discussions concerning the passivity of sense-impressions and the activity of spirit.

Two objections may occur to the reader. He may say, in the first place, that cognition is dynamic because it involves active attention. That is true, for the most part, although there are numerous exceptions unless the word 'attention' be misused, and

defined so as to include all degrees of inattention. It is not infrequent for ideas, and sometimes important ideas, to occur without any conscious effort of attention, and they sometimes dwell with a man when he makes no active effort to keep them before his mind. Apart from such exceptions, it is true that cognition implies attention, but cognition is never identical with attention. Attention is an attitude of endeavour, not of cognition. In it the subject seeks to fixate an object, to keep it before his mind, in order that he may see or understand what it is. Accordingly, attention ministers to cognition, but is not identical with it. If proof be required it is enough to point to the very exceptions mentioned above. How could a man ever entertain ideas without active attention, if attention were identical with knowing? The objection only illustrates how closely our different experiences are blended in the self, and how impossible it is to disrupt the self into isolated experiences. The consequences of that implication will be seen more fully in a moment.

The reader may object, in the second place, that to speak of experiences as dynamic, implies causal agency, and that it is quite impossible to understand experiences as either causes or effects. In what sense, he may ask, can we be sure that experiences of endeavour affect anything? If they do, as in the cases in which the striving for movement results in actual physical movement, it is clear, at all events, that no one can explain how a mental endeavour can affect a physical event (such as the movements of the brain), and therefore it is absurd to claim as a fundamental characteristic of certain experiences what is, to the last degree, doubtful and problematical. Or, again, he may say that when, in feeling, we maintain that an 'object' affects us, we are blind to the sense in which we have defined the term 'object.' If an object may be a presentation, or a universal, how can

these cause anything? A physical object, perhaps, can be a cause and can have effects, but physical objects are clearly not the only ones which affect our feelings. A mathematician may be delighted with his proofs, a philosopher with his arguments, an opium-eater with the visions revealed to his imagination. But neither proofs nor arguments nor dreams are physical objects, however intense the enjoyment they may cause. To these objections it is enough to reply that the analysis of this chapter is merely introspective. No claim is made to decide the ultimate questions of what causation means, or what can be a cause. The problem is far simpler and is only this; what do experiences *feel* like, and how do they reveal themselves to introspection? In that restricted sense the being of a feeling is to be passive, the being of an endeavour to act towards an object, and, in the same restricted sense, the analysis is not open to objection.

If the principle of this division is really fundamental for the analysis of mind it ought, at the same time, to furnish a positive basis for the constitution of mind. And it is manifest, on closer inspection, that it does. The members of the tripartite division are not isolated, though they are distinct, and they are not unrelated. Each has a positive function to perform in the economy of the self, none is unnecessary, all are complementary. The proof of this statement would require an exhaustive examination in detail of the characteristics of all experiences, and cannot be attempted within the limits of this essay since the matter of fact is infinite in richness and variety. But the sequel will afford numerous tests of the accuracy of the statement, and will show that it has not been arbitrarily or dogmatically assumed. Indeed it is possible to supply, in a tentative and provisional way, a formula for the general type of connection which exists between the

members of the tripartite division. Endeavour is *guided* by cognition and *prompted* by feeling. The principle of division involves, at the same time, a principle of connection, as every good principle of division should, and therefore it serves as a clue to subsequent enquiry.

We have now completed the analysis of the subject-matter of psychology, and have been led to results of considerable importance. In the first place we have seen that the subject-matter of psychology consists of acts of reference to an object; in the second place, that these acts are connected together by a principle. Since psychology is the positive science of mind, it might seem that the self can have no content other than that studied by psychology, and therefore that the only feasible line of enquiry into its nature is to pursue the clue of the connection of experiences, so far as we may. The sequel will decide whether such a course could be justified. Meanwhile, it is possible to affirm with some certainty that a 'cross-section' of the life of the self at any moment shows a plurality of experiences, fused and blended together. Broadly speaking, it consists of experiences of cognition, feeling and endeavour referring to some object and related together according to the formula described. There may be a preponderance of one of these elements or attitudes, *e.g.* the state of mind of a man who returns to consciousness from a fainting fit may be one in which feeling predominates over cognition or endeavour. But no one element is ever entirely absent. Not only *may* the elements be connected in the way described, they *must* be so connected; and this fact, for such it is, is an additional proof of the importance of the tripartite division. I have already remarked that it is impossible to have different cognitive attitudes simultaneously with respect to the same object, and that is also true of the 'qualities' of

feeling or endeavour. It is otherwise with the members of the tripartite division themselves. Not only may they occur simultaneously but they must so occur.

Now it may be true that a self or a soul over and above the experiences is required to explain even the unity of a momentary cross-section of its life. In any case the unity of the self is much more than this momentary unity. The cross-section is not self-subsistent. It has its roots in the consciousness of the past, it looks forward to the consciousness of the future. And it may seem that the existence of a soul is implied whenever such phrases as 'the way in which the subject is affected,' 'the life of the self,' 'our mental experiences' are employed. To have avoided these phrases would have been ridiculous pedantry, and therefore there is at least a verbal difficulty in the way of those who advocate the claims of psychology without a soul. 'Mind splits up into consciousnesses,' says Professor Titchener. 'A consciousness is a mental present . . . a bit of mind that is occupied with a single, however complicated, topic. Thus to put the matter crudely we begin the day with a getting-up consciousness: this is followed by a breakfast consciousness . . . etc.'<sup>1</sup> But who are the 'we' who begin the day, and does not the phrase 'a bit of mind' itself imply that very soul which Professor Titchener is so anxious to ignore?

I do not wish, in this place, to defend the theory of psychology without a soul. On that point, indeed, I find myself in substantial agreement with Husserl: 'The attempt to defend a psychology without a soul, corresponds to the theory of a science of nature without bodies. The first theory speaks of a psychology which abjures every metaphysical assump-

<sup>1</sup> Article 'Psychology' in *Encyclopædia Americana*. Quoted by Gruender, *Psychology without a Soul*, p. 29.

tion with regard to the soul: the second rejects in advance every theory that touches the metaphysical nature of the physical world.'<sup>1</sup> It is useless to pretend that any analysis can proceed without making assumptions, but that, in itself, does not show the futility of analysis. Perhaps a soul is required in addition to the psychical processes whose nature has been described. Perhaps these processes must, if they are thought truly, be thought as the states or the activities of an ego. Whether that be so, or not, it is certain that consciousness, even the consciousness of the moment, is not a mere unit or a collection of units, but involves a very intimate connection of different modes of reference to an object. And the unity and continuity of the self throughout the whole tract of time during which it exists is as ultimate and compelling a problem as this unity of a 'cross-section' at any particular moment. If the self were nothing but the unity of these experiences, it could not be explained without detailed considerations of the respect in which the experiences form a unity, and of why they must do so. The theory of a psychology without a soul must certainly be rejected if it implies the neglect of any of these considerations.

At the same time it is false that the use of personal pronouns, and the like, compels the inference that the self is more than a unity of experiences or that the stuff of the soul includes more than the subject-matter of psychology. The inference is not a necessity of thought or, even, an implication of speech. It depends merely on a misconception of the nature of analysis. 'Following life in creatures we dissect, we lose it in the moment we detect.' If analysis of the self really did dissect, then it would be impossible to reconstruct a self out of those *dissecta membra*.

If consciousness really split up into consciousnesses, then the splitting would doom this enquiry or any

<sup>1</sup> *Logische Untersuchungen*, Bd. II. S. 339.

similar one to fatuity. But analysis has no such implication, and if we could not analyse the nature of the self, we could only declaim about it, and could not think about it. It is possible, though not, perhaps, necessary or probable, that the term 'self' expresses nothing but the fact that any experience whatever forms part of a connected individual whole of experiences. There is no good evidence for any other sort of experience, for any 'floating' psychical state. And because of that, it is impossible to avoid the personal pronouns and other tell-tale terms. The terms express a profoundly important fact about the nature of consciousness. They do not assert the existence of a peculiar entity, or determine the answer to any particular metaphysical problem.

This problem, the problem of the soul, is the culmination of this enquiry. But it ought not to be approached without a careful and prolonged preliminary survey, and the aim of the earlier part of this essay is to perform that task. The broader aspects of the problem are plain enough, and are matters of general agreement. There are three principal questions at issue: 'What are experiences?' 'How are they united?' and 'What are the presuppositions of this unity?' The first of these questions has been discussed in a general way in the present chapter, the second and third are discussed continuously from the ninth chapter to the end of the volume, and the interval between the present chapter and the concluding chapters is occupied by the consideration of a range of problems which are too important to be neglected, and must be considered very fully if they are to be considered at all. There are risks in this procedure, and the chief of them is that the unity of the whole discussion may seem to be sacrificed to an undue preoccupation with mere detail. But that is a risk which must be taken.

First of all there is the problem of the relation of

the self to the body. The plain man considers that his body is part of himself. Is he right, or is he wrong? And, again, the body is frequently regarded as the permanent ground of the unity of the self. That problem, in various forms, is bound to arise at many points in this discussion, and the principal features of the problem are the subject of the next chapter. The discussion from the fourth chapter to the eighth (inclusive) has a somewhat different object, and the questions discussed in it include the majority of the problems which are usually considered to be, *par excellence*, the problems of the self. If it is granted that experiences afford the clue to the nature of the self, it is possible to argue from that basis to very different conclusions. For it may be maintained that some one particular kind of experiences reveal this clue with an adequacy which no other kind can approach. *Cogito ergo sum; sentio ergo sum; ago ergo sum.* Most of the arguments under this head fall naturally into the division of the primacy of feeling, will and cognition respectively, and I shall consider them in this order. The arguments for the primacy of will must obviously receive more attention than the others because they are more numerous, more persistently defended and, at any rate in appearance, more important.

I shall try to show that none of the great divisions of experiences has an invariable or essential primacy. Not merely is each of them essential and irreducible to any other, but the particular arguments in support of the primacy of any one of them cannot bear the test of critical scrutiny. Unless the question of primacy is settled, there is no possibility of an adequate discussion of the unity or the substantiality of the self. An answer to the question which is not precise and detailed is no answer at all, and too many of the current accounts of the self owe all their plausibility to a hasty assumption of the

primacy of will, or the primordial importance of sensation. If I succeed in avoiding a fatal error of this kind I shall at least have accomplished something. In a way the discussion in these chapters is a vindication and an explanation of the point of view which is outlined in the present one. But it is also more.

In conclusion, it is necessary to call attention to two points that must be constantly remembered in any discussion of the nature of the self. In the first place the self, as we know it, grows and develops in time, and different selves are widely dissimilar in the degree of their development. It would be comparatively easy to give an account of the self which would hold for a mature, harmonious and consistent personality. But difficulties thicken when we remember that even such fully-rounded personalities were once in their cradles and yet are supposed to form the same individual psychic centres throughout their lives. Indeed, if the arguments of Semon<sup>1</sup> or Samuel Butler,<sup>2</sup> on the subject of organic memory, have any weight, it is necessary to suppose that the beginnings of the psychical life of a single human self stretch back through many generations. Similarly it is necessary to give an account of garrulous selves as well as of silent ones, emotional selves as well as restrained ones, contradictory selves as well as logical ones. The general theory must be exceedingly elastic.

Finally, we must submit a theory which is able to take account of capacities and dispositions<sup>3</sup> as well as of actual events. I do not mean to say that a capacity in itself is an existent entity, but I must insist that the phrase is not meaningless. It is a commonplace that character is the most important constituent of personality, and character is most

<sup>1</sup> In *Die Mneme und Die mnemischen Empfindungen*.

<sup>2</sup> In *Life and Habit and Unconscious Memory*.

<sup>3</sup> For a further discussion of the precise sense in which these terms are used see Chap. X.

accurately defined as the capacity for responsible behaviour. But it is needless to suppose that a man's character is completely revealed to any one who is aware of all his actions, or even, *per impossibile*, of all his secret thoughts. Suppose, for instance, that we were acquainted with the inmost feelings of the man George Jeffreys when he browbeat offenders at the city sessions, when he embraced his favourites in his cups, as well as with the facts that he ordered Alice Lisle to the stake or that, when in prison, he was presented by his enemies with a barrel containing a halter instead of a barrel containing oysters. We should argue from these facts to his brutality, his sottishness, his cruelty and injustice, and we should thus understand the gift of the halter. But in so doing we should argue not only to the ways in which he *had* acted, and the thoughts which actually crossed his mind, but also to the ways in which he *would have* acted, had different circumstances presented themselves. In other words, we should include capacities, as well as actual behaviour. And this, accordingly, must be another feature of any true account of the self.

## CHAPTER III

### THE SELF AND THE BODY

PROBABLY no single question has been more fully discussed in modern philosophy than that of the relation between mind and body. Treatises upon the question appear continually, and some of them, Dr. McDougall's *Body and Mind*, for instance, are so admirably lucid, accurate and comprehensive that they hardly leave more to others than the useless opportunity of recounting a well-worn tale. There is still work to be done on the traditional lines, but such work would not be relevant in the present connection. In any case I do not wish to attack the question upon these lines. Instead of asking how we are to understand the relation of body and mind, I wish to ask whether upon careful reflection any parts or features of the body ought to be considered parts of the self. This road has, I think, been less trodden than the other. It deserves to be trod.

Unquestionably the body is the most important or, at least, an essential part of the self on many theories and for many men. 'That complex of frequent associations,' says Münsterberg, 'a complex which at first embraces only the presentations of our own body and its immediate environment, but in later years annexes the whole circle of our interests and ideals, is our very self, our personality.'<sup>1</sup> This

<sup>1</sup> *Die Willenshandlung*, S. 147.

analysis agrees very closely with James's account of the empirical self to which reference has already been made, and there can be no doubt that it represents a stage in the development of the idea of self, and corresponds closely to the popular, unreflective idea of self. But the reason for this is that early thought and popular thought cannot distinguish with sufficient accuracy between the physical body and the psychical self, and I do not see how any one, when he is fully aware of the meaning of the question at issue, can seriously maintain that his body is part of himself. It is natural and intelligible to say, 'Body, thou hast grown old along with me, and my infirmities have almost kept pace with thine'; but, unless we were Egyptians and believed in a double soul, it would be meaningless to substitute the word 'soul' or 'self' for 'body.' When we address our souls in soliloquy we are addressing ourselves. It is otherwise, however intimate the connection between body and mind, when we think of our bodies.

But while many would accept the principle, most remain blind to its implications, and in this chapter I wish to investigate these implications as precisely as possible. It seems to me that many bodily states are accounted parts of the self because there is a failure to recognise that they are really bodily. The investigation will lead to strange paradoxes—indeed, perhaps, to paradoxes so strange that it may seem simpler to deny the original assumption of this chapter. Be it so. The implications deserve to be considered.

I propose to begin this discussion by considering a well-worn phrase, now out of fashion, 'the internal sense.' The phrase is slightly equivocal as it includes 'innere Beobachtung' as well as 'innere Wahrnehmung,' to use Brentano's terms. 'Innere Beobachtung' is equivalent to introspection, and that is the meaning of the 'internal sense,' as the

term is used *e.g.* in Locke's *Essay*. 'The mind,' he says, 'receiving the ideas mentioned in the foregoing chapters from without [ideas of sensation, etc.] when it turns its view inward upon itself, and observes its own actions about those ideas it has, takes from thence other ideas, which are as capable to be the objects of its contemplation as any of those it received from foreign things.'<sup>1</sup> On the other hand 'the internal sense,' in the sense of 'innere Wahrnehmung,' means, not the acts of introspection, but the experiences which are the objects of such acts. The equivocation, however, if it be an equivocation, is easily understood. When the mind turns its eye inward, it contemplates those objects which are inward.

The criticism to which the phrase has been subjected seems very pertinent. 'Internal' refers to space, and consciousness is not extended nor does it occupy position. No doubt the analogous word 'introspection' has a metaphorical reference to space, but so has the phrase 'a close connection.' The metaphor in these cases is ignored. It is only an accident of etymology. But the word internal is more than metaphorical. It tends to be a literal statement, and if it is taken literally, what can it mean? Does 'internal' mean that which is enclosed within the periphery of the body, or some kernel yet more deeply hidden, the cortex, say, or some spot which philosophers or anatomists have seen fit to describe as the probable seat of the soul? In that case, we shall be told, it is utterly irrelevant to genuine introspection. And the word 'sense' is also misleading. The senses which we know are conditioned by some stimulus, and are correlated both with a peripheral and with a central organ. In what respect does the exercise of an act of introspection require a stimulus? And where is the organ of the internal sense? 'In-

<sup>1</sup> *Essay*, Book II. chap. vi.

ternal,' in fact, ought to mean 'mental,' and should not refer to a 'sense' at all. The phrase lingers only as a decrepit anachronism, deriving its sole significance from antithesis to an obsolete theory of sense-impressions. When the word impression implied Democritean phantasms, or Aristotelian 'sensible species,' which flitted into the mind's presence-chamber like airy sprites bestriding the gossamer, then it was necessary to invent a phrase to describe the contents of that presence-chamber itself. These were called internal because they never came in and could not go out. But when this cause of error is laid, the effect should also cease.

At the same time it may be doubted whether the objections to the phrase 'internal sense' are really so cogent as they appear. In the first place, the objection which rests upon the absence of a specific organ is irrelevant and external. The *nature* of sense-perception is never made clearer by physiology. A knowledge of peripheral organs and nerve fibres and central organs may help us to understand the conditions of sense-perception, but not its specifically mental features. And why, for that matter, should there not be a special organ for the internal sense, even if we use the term in the sense of introspection? That organ could not be a peripheral organ, but why should not acts of introspection have a special correlate in the cortex? I do not maintain that it must be so. On the scholastic theory the intellect has no cerebral correlate although all other experiences have, and the exception may also hold of acts of introspection. But why should it? The usual hypothesis is that there is a neurosis for every psychosis. The presumption, accordingly, is that acts of introspection, being a specific class of experiences, have a specific brain centre.

The internal sense, on its current interpretation, should have as its province whatever is 'in mind.'

The use of this phrase, however, is misleading. The antithesis between inner and outer is a heritage of 'the way of ideas,' and the word 'idea' is probably the most ambiguous in the whole realm of philosophy. An idea was defined by Locke as 'whatever is the object of the understanding when a man thinks'; and even Locke was too apt to consider that such objects are invariably of the type of sense presentations. This confusion became worse confounded when it was further assumed that every 'idea' was a modification of mind. In that case *every* idea was necessarily 'in mind,' since every idea was a modification of mind; and every modification of mind must, of course, be mental. It would follow that every object whatever was in mind, since ideas are the only objects of the understanding, and accordingly there would be no difference between internal and external.

It is true that Berkeley, at least, did not, or did not always, use the phrase 'in mind' in this misleading sense. 'Those qualities,' he says [*i.e.* extension and figure], 'are in the mind only as they are perceived by it-- that is, not by way of mode or attribute but by way of idea. And it no more follows that the soul or mind is extended, because extension exists in it alone, than it does that it is red or blue because those colours are on all hands acknowledged to exist in it, and nowhere else.'<sup>1</sup> The meaning of this statement is very clear. Berkeley has been dealing with the presentations of the external senses. These, he says, are 'in mind' in a certain sense. They are, in part at least, mind-dependent existences, and their being is to be perceived. But they are not parts or modifications of mind. They are not mental in the sense in which the acts and operations of mind are mental. Berkeley, indeed, although his psychology of the 'internal' sense is obscure, maintains that the acts of mind, those at

<sup>1</sup> *Principles*, § 49.

least which, following the example of Locke, he can classify as instances of 'perceptivity' and 'motivity,' are not presentations at all, although they are 'things' or 'objects' whose nature can be understood.

Even granting, however, that Berkeley was right in his interpretation, and that the 'internal sense' may be used legitimately with his meaning, the fact still remains that 'introspection' is the better term because it is the less likely to mislead. On the other hand there remains the possibility that the *literal* meaning of the phrase (and, especially, its *spatial* reference) may have considerable importance. It seems to me that it has, and that the literal connotation should never have been discarded in favour of the metaphorical. This is not merely a question of terminology, for there is no other term to express the precise spatial distinction which is in question, and that distinction is the crux of the problem of the self and the body, as it is considered in this chapter. I wish, then, to maintain (1) that the term 'internal sense' has a clear and legitimate meaning, although that meaning is neither synonymous with introspection nor with the objects of introspection; and (2) that the objects of the 'internal sense,' in this new signification, have no right to be considered parts of the self at all. That is the question at issue. Most of us would agree that the self must be distinguished from the body, and that anything revealed to introspection is part of the self; and the argument of this chapter presupposes the truth of that principle. I hope to show that the objects of the internal sense (in the signification I am defending) are really parts of the body, and therefore are *not* parts of the self. But they are liable to be confused, in many ways, with the objects of introspection, while their bodily features are quite unmistakable; and therefore both the psychologist and the plain man are apt to be hopelessly confused when they try to determine the

precise boundary between the body and the self. The ambiguity of the words 'internal sense' is a standing illustration of the ambiguity attaching to the things, and that is why the phrase was selected for discussion.

(1) If the words be taken literally the 'internal sense' ought to refer to that which is perceived within the body of the percipient, and the phrase 'external sense' to that which is perceived outside it. These are the specific objects of the 'internal' and 'external' senses respectively.

It may be objected that this distinction, while real, is utterly unimportant. Careful reflection, however, will show the contrary. What is it that is localised within the body? Is it not the pleasures and the pains of certain parts thereof, together with organic sensations, thirst and hunger? These form a different class of perceived objects, a different class of presentations, from those of the external senses. When we perceive the body of another, even under the dissecting knife, we have no presentations which differ in kind from those of the inorganic world. The body, like other presented things, is coloured, odorous, and the like. We know, theoretically, that our bodies, even within the mask of the epidermis, would be perceived in this way by others, and even, in the case of a minor operation, might be similarly perceived by ourselves. But, in general, the interior of the body is opaque to sight, or touch, or smell, and yet we are aware of it, and can localise sensations within it. Why should we deny that organic sensations, and the rest, are as truly parts of the body as anything which we, or others, can recognise through the other senses? There *really* is an internal sense whose objects are certain *real* states of the body. The acts of sensing these objects are parts of the self, but the objects themselves are not. The throbbing volume of an aching tooth is as truly a state of the physical

tooth as anything which the dentist can perceive through the aid of his instruments.

Consider, for instance, organic sensations,<sup>1</sup> feelings of fatigue, effort or strain, feelings of physical pain, of general nervous excitement, or the bodily unrest which often accompanies desire or expectation. In what way do these differ from the presentations of external objects if the word 'feeling' is used in its popular and not in its technical psychological sense? Both have quality, position in space, intensity, duration. Both are essentially presentations, material for acts of perception, not themselves psychical acts. They are objects for consciousness, not acts of reference to an object. A careful examination will show three distinctions that can be drawn, and will also show that no one of these distinctions is sufficient warrant for maintaining that the two classes of objects are in a fundamentally different category.

( $\alpha$ ) In the first place it may be said that the objects of the internal sense, especially in respect of

<sup>1</sup> The distinction between act and object ought to be drawn in the case of sensation as much as in any other, and the usual accounts of sensation suffer from neglecting the distinction. There is the act of *sensing* and the object *sensed*, and these are not one, but two. In the present chapter I have used the term sensation by itself, although with some risk of ambiguity. Any other course would have led to an irritating degree of repetition, and, besides, the term sensation is quoted so frequently in the discussion that no other course seemed practicable. The term sensation is usually employed as referring to the object rather than to the act. My contention is that acts of sensing are mental and their objects not, and the reader should remember this throughout the discussion. It should be unnecessary to add that the word 'object' is used in the broad sense explained in the previous chapter, and does not necessarily, or usually, mean a physical thing.

The view is sometimes maintained that the distinction between act and object applies to the level of *judgment* only, and that there is no difference whatever between the act of sensing and the object sensed, just as there is no difference between the feeling of a pleasure and the pleasure itself. The insuperable objection to such a view has already been mentioned. It is impossible to maintain that the mind is blue whenever there is a sensation of blue, while it is clear that the mind is pleased whenever there is a feeling of pleasure, in the strict psychical sense. Probably there is no instance of an act of sensing occurring apart from some degree of judgment, but, in that case, there is also no object sensed which is not also judged. And if the objects of judgment include, in any way, that which is sensed (and, plainly, they must include it) then the true analysis is that such acts of judgment include acts of sensing.

localisation, are vague and indefinite, while those of the external sense are definite and exact. We often feel toothache in the wrong tooth, and organic sensations are diffused, voluminous and massive, not definitely localised. This distinction may be true, but it is irrelevant. No one need maintain that the internal sense yields as definite information as the external. The question is only whether it has an equal claim to be called a sense. In our contact with the world we rely principally on the sense of sight. Instruments of measurement depend upon sight in the end. If we touch an object in the dark, we straightway attempt to visualise it. But the fact that sight is the most definite of the senses does not prove in any way that it is the only sense. The instances of erroneous localisation, similarly, only impugn the accuracy of the internal sense, and there is no reason to believe that such inaccuracy is very serious. Let us grant that the viscera are insensitive and that, when they are diseased, pain is felt in some other part of the body. If they are really insensitive it would be an error to localise pain in them. The disease causes pain—somewhere else. And that is where the pain is felt.

- (b) In the second place it may be maintained as an objection that the object perceived by the external senses is a real thing in real space. The objects of the internal sense are not real in this way. They are symptoms or indications of the real state of the body. The surgeon and the anatomist know the real nature and construction of the human body. When the patient relates his symptoms, he is only furnishing indications of that state.

Now if 'real thing' means only that there really is an object for consciousness, then that is true equally of the internal and external senses. In both cases there is something of which the mind is aware. But the statement, probably, means something different.

In all probability it means that the external senses take cognisance of a permanent, systematic, orderly, physical world whose character does not depend upon the fluctuating, private moods of particular percipients, and that the localisation<sup>1</sup> of objects of the external senses is a direct awareness of the spatial characteristics of *this* world. In that case the localisation of objects of the internal sense would be only secondary. We know or believe that organic sensations, and the rest, are connected with the real state of the body, and so we attribute to them, though falsely, specific spatial qualities.

The question of the nature of objects of sense-perception is clearly too large a one to receive adequate discussion in this place. Suffice it to say that if, in perception, there is direct awareness of a permanent, orderly world, that awareness is very imperfect and inadequate. It is at least equally probable that there is no such awareness, and that the objects of perception are subjective presentations which indicate the existence of a physical object in the sense of that term which has already been described in an earlier chapter of this essay. Each man, in all probability, sees a slightly different space, and for each man the space which he perceives by touch differs in important respects from that which he perceives by sight, though it may broadly correspond. On either theory there is no reason for maintaining an ultimate distinction between the external and internal senses in respect of the reality of their objects. If we believe that what we are aware of directly is a presentation indicating certain qualities in a physical object that is never directly perceived, then the presentations of the internal sense may certainly in a similar way indicate the state of our physical bodies. It is possible to

<sup>1</sup> In using the word 'localisation' I do not mean to imply the special sense in which it is (falsely, I think) distinguished from projection. I mean merely the attribution of spatial position in any kind of space.

argue from the pain of a patient as well as from his pallor, though the latter inference depends on sight, and the former on the internal sense. If, on the contrary, we believe that we directly perceive a real physical object, then why should not the pain in the tooth of an organism be as real a quality of the tooth as its colour? That is the natural assumption.

(c) The really important difference in the case is that the objects of the external sense are common to many percipients while those of the internal sense are peculiar to a single percipient. The nurse, and the surgeon, and many others may see the wound, only the patient feels the pain. That is a proof of the *subjectivity* of intra-organic percepts, but it is no disproof of the possibility that they are really states of the body in the sense in which any percept is real. They are percepts because they involve the spatial co-ordination and the objective reference implied by that term. To prove them subjective does not prove them psychical or parts of the self. It only proves that they are objects which cannot be perceived by any other self.

The fact on any theory is doubtful, for on any theory a certain taint of subjectivity clings to the objects of sense-perception. What we perceive, on any theory, depends partly upon us. It is not a purely impartial view of the object. After-sensations are blended with the objects of vision since the chemical processes in the retina are comparatively slow and the eye, in this respect as in many others, is by no means an adequate instrument of vision. It is not merely santonine powder or jaundice which perverts colour vision. There are minute individual idiosyncrasies which affect the act of every percipient and similar individual differences occur in the case of every object perceived. But this circumstance emphatically does not prove that what is perceived is part of mind. It is only mind-dependent in certain

respects. This consideration leads to the second question to be discussed. The objects of the internal sense should not be confused with the self. Although they differ in many respects from the objects of the external senses, they are at one with these in being objects for the conscious self, not parts of it. But it is also advisable to consider which of the objects of the internal self are commonly accounted parts of the self, and why this confusion is made.

(2) The question has very considerable importance in view of many of the issues raised by modern psychology, and a consideration of these issues will include the whole range of this debatable ground between the self and the body. Let us examine them from the standpoint already indicated. There is a reference to recent controversies with respect to the somatic resonance implied in emotion. There is the implication of one of James's numerous accounts of the nature of activity, accounts in which even the 'spiritual self,' the self of selves, is said to consist of a collection of movements in the head and throat. There is the problem of the distinction between psychical and physical<sup>1</sup> pain, and that of the important part which many purely bodily conditions appear to play in dissociations and alterations of personality, and in many of the delusions of the insane. True, the psychologist need not attempt to cover the whole ground traversed by the modern alienist. It is as little relevant for him to enquire, whether every sort of insanity is due to toxic influence as to attempt to discover an anti-toxin for *paranoia*, or *dementia praecox*, or *folie circulaire*. His proper task is to distinguish carefully between states of the body and mental experiences proper. Defective analysis in this respect frequently

<sup>1</sup> The word 'physical' is here used somewhat loosely to indicate that which is referred to as pertaining to the body. The reader must remember the distinctions drawn in Chapter II., but no serious ambiguity need arise from this lack of precision.

leads to false conclusions, and the idea which many a man has of himself is really an idea of his body to an extent that would astonish him greatly were his attention called to the fact. This, in itself, is not surprising. Analysis is notoriously difficult, and the obvious subjectivity of all objects of the internal sense leads easily and naturally to a confusion with selfhood. Moreover, there is yet a further respect in which the difficulty of introspection is aggravated in this case. Certain characteristics of objects of the internal sense seem to link them inextricably with the objects of genuine introspection.

It is really an old question, this, though it is perennial; the issue, almost in the sense in which it arises here, can be clearly seen in the writings of Descartes, Locke and others. All readers of Descartes know that he believed, despite his dualism, in a very intimate relation between body and mind.<sup>1</sup> The mind, he said, could not be merely a spectator of the doings of the body. The relation between the two [to use a metaphor already employed by Aristotle] must be more intimate than that of a pilot to his ship. The soul and the body, for Descartes, formed a *mélange confus*, and the fact appears most clearly, if not solely, in those puzzling states of pleasure and pain, which the Creator implanted in man in order that he might maintain his bodily estate. But the examples which Descartes chooses are not merely those of pleasure and pain, but such states as those of hunger and thirst, and it is clear from the context that he regarded these states as pertaining equally to the soul and the body (if he did not believe them to be a third species of existence which partook, in an indeterminate manner, of the nature of each). They yield a confused acquaintance with the body in much the same sense as colours and tastes yield a confused knowledge of the qualities of the real

<sup>1</sup> *Meditations*. vi.

physical object. Indeed it is difficult to see why Descartes thought that these states partook more of the nature of thought than other secondary qualities. The fact that they aid and abet the welfare of mankind is nothing to the purpose. For on Descartes's theory, and on that of Locke and Berkeley too, one of the chief functions of every sense is to teach mankind what to pursue and what to avoid. On Locke's theory we do not know, by our senses, the minute constitution of bodies, and on Berkeley's theory sense is but a symbol of the divine reality. In both cases it is part of the being of sense-perception to guide us in the conduct of life.

But Locke is much more emphatic than Descartes. 'We have some kind of evidence in our very bodies that their constituent particles, whilst vitally united to this same thinking conscious self, so that *we feel*<sup>1</sup> when they are touched, and are affected by, and conscious of, good or harm that happens to them, are a part of ourselves; *i.e.* of our thinking conscious self. Thus the limbs of his body are to every one a part of himself; he sympathises and is concerned for them. Cut off a hand, and thereby separate it from that consciousness he had of its heat, cold and other affections, and it is then no longer a part of that which is himself, any more than the remotest part of matter.'<sup>2</sup>

Locke maintains, therefore, that the limbs and other parts of the 'body are thought to be parts of the self because of our interest in them and our sympathy for them. But it seems clear, despite Professor James and others, that this sense of the word is metaphorical. Because a man is interested in philately it does not follow that he is, in any sense, composed of stamps. Locke, however, and Descartes also, were influenced by other considerations, prin-

<sup>1</sup> Italics Locke's.

<sup>2</sup> *Essay*, Book II. chap. xxvii. § 11.

cipally by those concerning the nature of feeling. Indeed the passage from Locke seems self-evident until the question of the meaning of feeling is carefully considered; and even then, as we shall see, there is something to be said in favour of his argument. *We feel* our body, and feeling is distinctly and characteristically psychical, but the word feeling is ambiguous. When we speak of feeling our limbs, or the like, we refer to a sort of perception or sensation, and this implies a psychical act of reference and an object presented. 'Feeling' in a strictly psychical sense means something different. It is wholly and entirely an experience and is not a sort of cognition as acts of perception or sensation are. At the same time there are close analogies between 'feeling' as a psychical experience and 'feeling' as including objects of the internal sense. We can only understand the position of Descartes or Locke if we take account of those analogies.

Feeling, as a psychical experience, is passive in character; it is the affective aspect of consciousness. And it is also subjective in a marked degree even if it be not 'subjectively subjective' in precisely Hamilton's sense. But although passivity or activity form no part of the attitude of cognition, and therefore no part of the attitude of sensation or perception, none the less our percepts and the objects of sensation seem thrust upon us from without and are independent of the control of the will. This is one of the respects in which they are distinguished from the objects of imagination or intellection. If I am in Paris and open my eyes I must see the town in a certain way, but if I imagine Paris to be the New Jerusalem I can picture the Seine as clear as Abana or Pharpar, or yellow like the Tiber, I can picture the Panthéon as composed of rubies and amethysts, and place it by the side of Nôtre Dame in the Champs Elysées. Thus in respect of passivity *any* object of

sensation or perception (and the objects of the internal sense are included in this class) is ranked along with feeling, although the passivity of psychical feeling may differ from this passivity in important respects. And, again, the objects of the internal sense are certainly subjective, since they can only be perceived by a single person. That is the characteristic which is common to the 'internal sense' and to introspection, and it occasions much of the confusion between them. But we have already seen that it is logically irrelevant, however natural the misconception to which it gives rise.

In the third place psychical feeling plays a part in the life of the self which is analogous to the part which physical feeling plays in the life of the organism. In accordance with our previous account, though without any implications of temporal order, we may say that feeling looks behind to cognition and before to endeavour. Similarly the internal states of the organism are a connecting-link between the stimulus received from the environment and the reaction towards that environment. It is a rough analogy, no doubt, but in one way or another it influences discussions on this question. Let us take this statement, for instance :

'It was said above that every instinctive process has the three aspects of all mental process, the cognitive, the affective and the conative. Now the innate psycho-physical disposition, which is an instinct, may be regarded as consisting of three corresponding parts, an afferent, a central and a motor or efferent part, whose activities are the cognitive, the affective and the conative features respectively of the total instinctive process. The afferent or receptive part of the total disposition is some organised group of nervous elements or neurones that is specially adapted to receive and to elaborate the impulses initiated in the sense-organ by the native object of the instinct ;

its constitution and activities determine the sensory content of the psycho-physical process. From the afferent part, the excitement spreads over to the central part of the disposition; the constitution of this part determines in the main the distribution of the nervous impulses, especially of the impulses that descend to modify the working of the visceral organs, the heart, lungs, blood-vessels, glands and so forth, in the manner required for the most effective execution of the instinctive action; the nervous activities of this central part are the correlates of the affective or emotional aspect or feature of the total psychological process.<sup>1</sup>

The phrases afferent, efferent and central can only refer to the physical part of the psycho-physical disposition, and even in that case there would be no special reason for supposing that the afferent nerves (or their central nerve-endings) were correlated with cognition, the efferent with conation, and the central with feeling. On the contrary, there is every reason to believe that there is no *Innervationsgefühl*, and consequently that our *cognition* of motor activity is sensory in origin. Nor, again, should the argument be used that the feelings connected with speculative thought are differently related to it than other feelings to other kinds of cognition. Yet in the case of this kind of cognition there is no reason to believe in any afferent nerve process, as there is no reason to believe that any external stimulus whatever enters. Dr. M'Dougall's analogy, therefore, has no especial importance even in the case of instinctive actions to which he refers. I have mentioned it only because the analogy seems to weigh with some who consider bodily feelings, or some special class of bodily feelings, parts of the self. Dr. M'Dougall's argument refers only to cerebral localisation, not to the awareness of states of the body; but the same analogy might be

<sup>1</sup> M'Dougall, *Social Psychology*, pp. 32, 33.

applied equally well to the body as a whole. The body as a whole is obviously intermediate, even in point of time, between stimulus and reaction.

The passage is also an excellent introduction to a discussion of the distinction between bodily 'feelings' and psychical feelings. It is because the two are confused that the body is considered a part of the self. Let us begin by considering emotion. That surely is a part of the self. What is more intimately part of our being than our love and our hate, or the rarer states in which poetry or music flood the soul with feeling? The older theories of emotion treated emotion from the point of view of psychical feeling, and they were right in doing so. But the modern treatment lays chief or sole emphasis upon an entirely different aspect, the bodily aspect, and this aspect is also relevant. I cannot consider this question as fully as it deserves, but it is impossible to avoid dealing with it in considerable detail.

Modern interest in the question of the nature of emotion was greatly stimulated by the arguments of Professor James. His theory of the emotions is closely connected with his views upon instinct. Under the term instinct he seems to include every impulse, at any rate he maintains that every instinct is an impulse. The meaning of the term impulse is not so clear. He seems to mean that every bodily adjustment, simple or complicated, is an impulse, and also that any kind of ultimate preference or liking is an impulse. This usage is very misleading, for what is there in common between a cough or a sneeze and a preference of champagne to ditchwater?<sup>1</sup> It is probably true that every instinct involves physiological reflexes and impulses; and is connected with ultimate likes and dislikes, but it does not follow either that these preferences are simply the awareness

<sup>1</sup> These examples are all chosen from Professor James himself. See his *Principles of Psychology*, vol. ii. pp. 403 and 386 respectively.

of physiological events, or that a conscious instinct is only the awareness of such events. Professor James is more concerned with psychological analysis than with coherent psychological theory. The view which he defends in connection with the instincts and emotions is that psychology depends upon physiology, and that consciousness is to be explained by reference to a complicated system of physical reactions together with the connected reflex arcs.

It is usual to maintain that an instinct is a sort of racial habit belonging to every member of a given species; that it is complex and co-ordinated like the actions of a bird in building its nest; that it is biologically advantageous to the species concerned and tends towards its maintenance and development, although the individuals who act instinctively need not have any conscious awareness of that end; and that, although it may be perfected through experience, it does not require previous experience as a condition of its occurrence. These characteristics, collectively (and for the most part severally), are sufficient to distinguish instincts from impulses. On Professor James's definition it is unnecessary to draw this distinction at all.

He proposes, however, to consider an emotion as almost indistinguishable from an instinct. The expressions of the two are almost identical and, as we shall see, it is the awareness of the expression of emotion which is the *differentia* of the total emotional state. 'Instinctive reactions,' he says, 'and emotional expressions thus shade imperceptibly into each other. . . . Emotions, however, fall short of instincts, in that the emotional reaction usually terminates in the subject's own body, whilst the instinctive reaction is apt to go farther and enter into practical relations with the exciting object.'<sup>1</sup>

James's analysis of the emotional state is as follows:

<sup>1</sup> *Principles of Psychology*, vol. ii. p. 442.

Owing to the extreme range and variety of instincts, or, as we should say, of instinctive bodily reactions and impulses, an indefinite number of bodily changes may occur in connection with particular thoughts, and it is a universal law that consciousness is necessarily correlated with bodily movement. 'The whole neural organism, it will be remembered, is, physiologically considered, but a machine for converting stimuli into reactions; and the intellectual part of our life is knit up with the middle or central portion of the machine's operations. . . . Every impression which impinges on the incoming nerves produces some discharge down the outgoing ones, whether we be aware of it or not. Using sweeping terms and ignoring exceptions, we might say that every possible feeling produces a movement, and that the movement is a movement of the entire organism, and of each and all its parts.'<sup>1</sup> The whole organism, therefore, may be compared to an indefinitely complex and varied sounding board. When we consider its reactions, and to these we are restricted in the case of emotion, we have before us complex waves of 'somatic resonance.' This somatic resonance is the crucial feature of his account of emotion, and its complexity is at least equal to the complexity of man's emotions—the most complex of all his experiences.

Now in any emotional state there is both an act of cognition and a feeling of this somatic resonance. We perceive some object and our emotions are aroused, or we think of some idea associated with this object and the same result happens. On reflection, however, we do not find that this perception or this idea differs from other perceptions or other ideas. Acts of cognition are, invariably, cold and neutral, whether they occur in a state which, as a whole, is emotionally tinged, or whether they do not. The *differentia* of emotion, accordingly, cannot be found in this element

<sup>1</sup> *Principles of Psychology*, vol. ii. p. 372.

of the emotional complex. James's theory is that it belongs to the other. 'My theory is that the bodily changes follow directly the perception of the exciting fact and that our feeling of the same changes as they occur is the emotion.'<sup>1</sup> 'The emotion, therefore, is, strictly speaking, a sort of *sensation*. The emotions are *sensational* processes, processes due to inward currents due to physical happenings.'<sup>2</sup> And it is undeniable, not only that there is this somatic resonance, but also that it is felt, obscurely or acutely, the moment it occurs. 'Our whole cubic capacity is sensibly alive; and each morsel of it contributes its pulsations of feeling, dim or sharp, pleasant, painful or dubious, to that sense of personality that every one of us unfailingly carries with him. It is surprising what little items give accent to these complexes of sensibility. When worried by any slight trouble, one may find that the focus of one's bodily consciousness is the contraction, often quite inconsiderable, of the eyes and brows. When momentarily embarrassed, it is something in the pharynx that compels either a swallow, a clearing of the throat, or a slight cough; and so on for as many more instances as might be named.'<sup>3</sup>

Although there is a difference between the older and the more recent treatment of emotion, it would be false to suppose that most modern psychologists agree with James. On the contrary, the balance of authority is against him. But his friends and his foes both admit that the sensational elements to which he accords so much prominence are really important and profoundly important constituents of the total emotional state. His opponents, however, argue, like Professor Stout in his *Manual of Psychology*,<sup>4</sup> that James's argument 'lacks logical stringency.' He rests his case upon the assertion

that without the somatic resonance there would be no emotion, and it no more follows that the resonance is the emotion than that a man's vision is his spectacles because he cannot see without them. That criticism is unfair because James's argument does not require logical stringency. It is not a logical demonstration, but primarily an appeal to introspection, and it should be met on this ground. I shall, accordingly, avoid other arguments, some of which appear to me sound, and others mere misunderstandings.

Let us take the point raised in the last quotation from the *Principles of Psychology*. It is probably true that there is a contraction of the eyes and brows when we are annoyed, and that we feel something in the pharynx when momentarily embarrassed. But we are not usually aware of these facts until our attention is drawn to them. They may conceivably be felt obscurely, but certainly not acutely. At the same time the annoyance or the embarrassment is felt acutely and is certainly a real state of feeling, not merely a cold and neutral intellectual apprehension. This, I think, is obvious on reflection, and I cannot find, in my own case at least, that the result of the analysis is appreciably altered by the remembrance that the contraction of the eyes and brows is not the whole of the somatic resonance in question.

It is true that James's account refers primarily to the coarser emotions, but even in their case it is possible to detect the same difference. Fear is accompanied by dryness of the mouth, by goose flesh, by altered circulation, and so forth. But it will be found that we are frequently aware of these *before* we are really afraid, just as we also find that these manifestations may continue long after the psychical excitement has passed. Although, then, the bodily sensations and the psychical feelings are blended together and frequently indistinguishable, still, in the

main, we *can* distinguish the two even in those cases which are most favourable to James's case.

The attentive reader of the *Principles of Psychology* cannot fail to notice that James habitually supposes consciousness to be synonymous with cognition. On that assumption there is no other analysis open to him than the one he actually adopts. The emotional state is certainly not merely cognitive, and therefore the *differentia* of emotion must be sought elsewhere. If that *differentia* cannot be found in consciousness, organic sensation is clearly its probable source, especially when the concomitance of organic sensation with emotion, and its relevance for emotion, can be demonstrated. But if consciousness and cognition are not synonymous, the burden of proof rests with James, and he has not examined that burden fully. His most characteristic arguments with regard to activity are open to the same criticism, but it is convenient to consider the distinction between psychical and physical pain,<sup>1</sup> before proceeding to the question whether activity is really bodily and nothing else. The question of the distinction between pain as a psychical experience and as an organic sensation ought to be decided by reference to two characteristics: (1) whether there is localisation within the body; (2) whether there is conscious reference to an object. If the former, then the reference is to sensations which are objects of the internal sense but no more parts of the self than any other presentations, and are 'in mind' only in Berkeley's sense, if at all. If the latter, the reference is to experiences proper.

Analysis in this question is certainly difficult. There seems a balance of probability that pain spots exist on the surface of the body, in the same sense as spots peculiarly sensitive to heat or cold, although

one possible analysis is that pain is always psychical, but so intimately connected with certain bodily sensations that it is localised where they are localised. The localisation would, in this case, be an error, but it would be an error most incident to psychology. 'It is through the character of the accompanying sensation that we are able to distinguish different kinds of organic pain and pleasure. Thus we discriminate from each other stinging, piercing, gnawing, crushing, beating, shooting and other innumerable kinds of pain.'<sup>1</sup> These characteristics are undoubtedly physical, and the class of pains which is relevant in this connection is so intimately bound up with them and so definitely localised, that the presumption is that the pain also is as much a matter of sensation or perception as its features of shooting or burning. On the other hand, aesthetic pleasures, and the like, are not localised in the body, and seem to refer to an object, although this latter characteristic has not been sufficiently discussed hitherto. The pain which is a sensation cannot be said to refer to an object in any sense.

The very fact that the question can be raised shows how kindred in nature and similar in effects certain psychical feelings and certain states of the body are, and it is because of this blending and this similarity that there is so much truth in Descartes's position. Descartes had reason for maintaining that the relation of a man to his body is something *sui generis*, something he may naturally believe a part of himself. The facts previously adduced show this clearly, and when we remember also that the body is a constant seat of interest, a constant instrument for action, we see, more and more clearly, the reasons which determine the plain man to adopt the view he does. Some bodily sensations are very like real

<sup>1</sup> Stout, *Manual of Psychology*, p. 226. (The references, here and elsewhere, are always to the first edition, unless otherwise stated; and any difference between the editions is noted.)

psychical feelings. Moreover, they are usually much alike in the way they influence conduct. The philosopher is quite as impatient of toothache as he is of the pain of a contradiction. He is thwarted by both in a way that pierces his being, and although, if he is strong in will, he can dismiss either for a brief space, he is impelled to seek every means in his power to bring the unsatisfactory state of affairs to an end.

Let us consider some other ways in which bodily sensations are apt to be confused with psychical experiences, and so with the self. In the tangled mass of evidence relating to alternation and dissociation of personality, one fact stands out clear and indisputable. The principal factor which leads to such disintegration is not merely a change in emotion and mood, but the organic sensations connected with it. Loss of sight or hearing does not have this effect, nor do hallucinations except when conjoined with changes in coenaesthesia and organic tone. The attentive student of the Beauchamp case<sup>1</sup> will have noticed this fact in every one of Miss Beauchamp's alternating phases, as also in her distinction from 'Sally.' As this evidence falls for more detailed consideration in a later chapter, it need not be fully considered here. It is enough to remind the reader of the connection between the various personalities in the case of Louis Vivé, and the various degrees of the anaesthesia of their common body, or to ask him to consider those cases which led M. Ribot to formulate his 'colonial' theory of the self.<sup>2</sup> In such instances (occasionally) there seems to be a contradiction. The subject declares that *he* knows that *he* has become a different person. But even a normal subject is apt to contradict himself, and the only inference is that the subject, in these instances, seizes upon a feature which he is wont to consider an important, or the

most important, part of himself, viz. a certain continuous tone of bodily sensation. When that oscillates between two states which have each a characteristic coherence and continuity of its own, then the subject is at a loss. He retains his memory, but an essential part of what he is accustomed to call himself has suddenly disappeared. And therefore he contradicts himself. It is far more important to discover the grounds of this contradiction than simply to point it out. And in those cases of hysteria in which various apparently different personalities refer to one another as *l'autre*, or *l'idiot*, or *le scélérat*, there is, at least, no contradiction.

Professor James's account of the nature of personal identity relied chiefly upon this class of facts. He was certainly in error when he assumed that the question of the nature of the pure ego was the same as that of the nature of personal identity. The 'pure ego,' if it exists, is nearer of kin to the 'spiritual self,' although hardly in the sense in which he uses that term. This, however, does not necessarily affect the accuracy of his analysis of personal identity, which he states as follows.

A judgment about personal identity is logically on the same plane as any other judgment of identity. As in any other instance, the judgment refers to the identity of the object about which it is made. What is identical is not an act of appropriation, but that which is appropriated. The object of this thought, that which it consciously appropriates, must be part of the empirical self, and the nucleus of this self is feeling. Thought (James argues against the associationists) is not itself a presentation, and personal identity must be sought in the identity of those presentations which the thought appropriates as specifically its own. Certain bodily feelings are the most significant of such presentations, and form the real core of personal identity. It is the identity of these presentations,

especially of the adjustments which accompany affirmation, denial or endeavour, that form the only sort of activity which introspection can discover. To speak of the identity of these presentations is to speak of the 'warmth and intimacy,' or the 'animal aroma,' which invariably clings to them. 'Warmth and intimacy leads us to the answer sought. For whatever the thought we are criticising may think about its present self, that self comes to its acquaintance, or is actually felt, with warmth and intimacy. Of course this is the case with the bodily part of it: we feel the whole cubic mass of our body all the while, it gives us an increasing sense of personal existence. Equally do we feel the "inner nucleus of the spiritual self," either in the shape of yon faint physiological adjustments, or (adopting the universal psychological belief) in that of the pure activity of our thought taking place as such. (Our remoter spiritual, material, and social selves, so far as they are realised, come also with a glow or a warmth; for the thought of them infallibly brings some degree of organic emotion in the shape of quickened heart-beats, oppressed breathing, or some other alteration, even though it be a slight one, in the general bodily tone.'<sup>1</sup> This all-important factor of 'warmth and intimacy' is, therefore, a *bodily* factor. It is because of the evaporation of animal heat that the grown man feels that his life is foreign to that which he lived when a child. 'No sentiment of his little body, of his emotions, of his psychic strivings as they felt to him, comes up to contribute an element of warmth and intimacy to the narrative we hear, and the main bond of union with our present self thus disappears.'<sup>2</sup>

It is true that personal identity, being the identity of a person, is logically on the same footing as any other sort of identity. It is true, also, that at least

<sup>1</sup> *Principles of Psychology*, vol. I. p. 333.

<sup>2</sup> *Ibid.*, p. 335.

the best starting-point for a discussion of personal identity is to be found in the identity of the self as it appears to introspection. But if the previous argument holds, the body is not the self at all, and its animal aroma, however interesting and however profoundly connected with the life of the self, is not part of that life. 'Warmth and intimacy,' then, if literally understood (and Professor James means it to be taken literally), is at most an *indication* of personal identity and not itself part of the person at any time. Moreover, James himself lays undue stress upon it, as is clearly implied in one of his examples. The psychic strivings of the child, his juvenile breaches of decorum and the like, have neither warmth nor intimacy when the child becomes a man. But the grown man, none the less, continues to believe that he is the same psychic centre which, twenty or more years before, teased his comrades and plagued his schoolmaster. And even if we concede for the sake of argument that the body, or part of it, is part of the self, still we must also maintain that personal identity includes more than a continued warmth and intimacy. What of the identity of cognition revealed by memory? Do we never remember cognitive and other experiences directly? Do we always base our remembrance, which is, and must be, personal, upon this identity of animal aroma? There is another oversight in Professor James's account. It is not very easy to reconcile the statement (p. 340) that 'the thought never is an object in its own hands' with the careless grace with which the concluding paragraph of the chapter (p. 401) leaves the question entirely open whether or no 'we have any *direct* knowledge of thought as such.' The problem, once more, is the possibility of introspection, and it is defective analysis on this point which has led James into error. He saw that psychical processes, or at least processes of cognition, are not primarily presentations or 'objects,'

and he also perceived that the attempt to discover the nature of personal identity implies the consideration of the identity of a certain kind of object in the same sense as in any other case of identity. But psychical processes, though not primarily objects but references to an object, may themselves be objects of another psychical act. And if these psychical acts are not the sole constituents of the self, they are at any rate among its most important constituents, and their identity, accordingly, among the most important questions to be discussed.

A few words will suffice on the question of activity. According to James, if we ask what activity feels like, we find that it consists in a feeling of some bodily processes taking place, for the most part within the head. 'The self of selves, when carefully examined, is found to consist mainly of the collection of these peculiar motions in the head, or between the head and throat.' This is the spiritual self, according to James, and if his account is true it is hard to see why the consent of mankind assigns the bodily self to the bottom of the scale of values and the spiritual self to the top. James mentions the fact, and does not even protest.<sup>1</sup> But the experience of activity should not be confused with these accompanying states of the body. Feelings of effort may be bodily, and so may feelings of strain; but these are different from psychical endeavour. Congenial work gives scope to much endeavour, but not necessarily to appreciable effort or appreciable strain. Effort and strain refer to the overcoming of obstacles, not to the degree of endeavour. I shall discuss this question more fully later. At present it is sufficient to mention it.

I have said enough to indicate which bodily presentations are frequently accounted parts of the self, and I agree that, in many instances, it is paradoxical

<sup>1</sup> *Principles of Psychology*, vol. i. p. 313.

to deny that they are such parts. At the same time it seems clear that these sensations, the objects of the internal sense, stand on no different footing from other sensations, and, if that be true, they ought not to be considered parts of the self. They have no right to be considered parts or modifications of mind, and that is the crux of the question. They may be subjective, they may be analogous to feeling, they may be always present, their absence may lead to doubt of the continuance of personal identity. All these considerations are irrelevant to the main point at issue.

Although this chapter has already extended to too great length, it is necessary to mention two other points. First of all, there is the problem of the sense in which consciousness occupies position. Consciousness is not extended, but most men would consider that one self is in a different place from another, and, to use Locke's illustration, can 'travel in a coach from Oxford to London.' There is nothing unnatural when Macaulay says of Byron that 'he carried his exhausted body and his wounded spirit to the Grecian camp.' I was in Dresden, and am now in Paris. Would it seem equally natural to say, 'The physical body which I call mine, or have reason to believe is closely connected with my self, was in Dresden and is now in Paris'? Is it not the plain, unvarnished truth that a given self is in a given place, and was not Mrs. Crisparkle right in asserting that 'a man must be somewhere'?

'To be in a place' (I quote from Lotze) 'means simply and solely to exert action from that place and to experience the actions or effects that reach that place.'<sup>1</sup> Or, again, 'Wherever there are elements with which the nature of the soul enables and compels us to interact, there it will be present and active; wherever there is no such summons to action, there

<sup>1</sup> *Metaphysic*, English translation, vol. ii. p. 284.

it will not be, or will appear not to be.'<sup>1</sup> These statements have frequently met with assent, but do not seem true if carefully considered. To occupy position is one thing, to exercise causal influence quite another thing. It is perfectly conceivable that something should have position and yet should exercise no causal influence whatever. It is true that light does work certain physical effects, but no contradiction is involved in supposing it not to do so, and yet in ascribing position to it. Conversely, there is the theoretical possibility that some being, not in space, should exercise causal influence even upon beings who are. Let us suppose that God, at sundry times and in divers manners, has wrought miracles. Does it follow that He is in space?

There is a paradox which results from Lotze's theory. If the theory is true it follows that on parallelistic theories, since the sole giver or receiver of spatial effects is the body, the mind cannot be anywhere. On interactionist theories, on the contrary, since the mind has direct dynamical influence upon the brain if not upon the body at large, it would follow that the mind is extended!

If cognition is regarded as a light which sheds its beams without imparting or receiving effects, then it is true that cognition occupies the position of the object to which it refers, and a similar account might hold good of other experiences. In that case, if a man looked from the sands towards a lighthouse far out to sea, the position of his mind would be the whole stretch from his eyes to the lighthouse. But the fact that in such perception the body is a pivot, that if he turns round he perceives not ocean but sand, would be enough to lead to the reflection that the mind, in a special sense, has its abode in the body. Moreover, certain acts of physical adjustment, which are phenomena of the internal sense, form the chief

<sup>1</sup> *Metaphysic*, English translation, vol. II. p. 289.

data for estimating the spatial position of objects. In short, if position must be assigned to consciousness, then the only possible course is to maintain that an experience occupies the position of the whole range of objects to which it refers at any given time. It should never be localised in the brain, for that is only the instrument of consciousness. And if it be a paradox that consciousness may extend from the earth to the stars, because of the power of human vision, the paradox disappears on closer reflection. The range of the other senses is very small, and in touch, the most important of them, extends only to the horizon of the sweep of the arm. The range of endeavour is similarly restricted to the body, so far as action is concerned. And many experiences, on this theory, occupy no position whatever, since they refer to the universal 'or, perhaps, the imaginary. The complications, in fact, are so great that it is best to avoid them altogether. To ascribe position to consciousness is more metaphorical than useful.

In the second place, there is a deeper problem still. It might seem, indeed, as if this whole enquiry had taken a wrong direction. Why distinguish body from mind at all? May not the *living* body be the self? This conjecture, under the form of the double-aspect or double-attribute theory, has always been considered, but certain modern writers maintain it in a new form, which does not seem identical with these theories or with materialism. Professor James has written a powerful essay on the question, 'Does Consciousness exist?'<sup>1</sup> and he argues that the word consciousness does not stand for an entity but only for a function. 'I could perfectly well define, without the notion of consciousness, what the knowing actually and practically amounts to—leading towards, namely, and terminating—in percepts through a series of transitional experiences which the world supplies.'<sup>2</sup>

<sup>1</sup> *Essays in Radical Empiricism*, pp. 1-38.

<sup>2</sup> *Ibid.* p. 25.

'The I think which Kant said must be able to accompany all my objects, is the "I breathe" which actually does accompany them. There are other internal facts besides breathing (intra-cephalic muscular adjustments, etc., of which I have said a word in my larger *Psychology*), and these increase the assets of "consciousness," so far as the latter is subject to immediate perception; but breath, which was ever the original of "spirit," breath moving outwards, between the glottis and the nostrils, is, I am persuaded, the essence out of which philosophers have constructed the entity known to them as consciousness. That entity is fictitious, while thoughts in the concrete are fully real. But thoughts in the concrete are made of the same stuff as things are.'<sup>1</sup>

This view has an engaging simplicity, but it achieves this simplicity, at least in the form in which it is stated by Professor James, by ignoring some fundamental distinctions. Consciousness is essentially reference to an object, but it does not follow that anything which leads to or terminates in a percept is *eo ipso* aware of that percept, or strives towards it, or feels with regard to it. If a derelict leads towards or terminates in a reef, the derelict is not therefore conscious. And if percept, by way of reply to this objection, be distinguished from thing, what is this but the flat denial of the truth of James's contention? No philosopher is constrained to construct either an 'entity' consciousness or a 'function' consciousness out of such results. A percept is not an experience but an object of experience, and the world does not supply transitional experiences between percepts, while it does supply transitional percepts. I shall be told, no doubt, that this criticism is the product of philosophical sophistication. In a world of pure experience the distinction between a conscious act and its object does not apply. The reply is obvious;

<sup>1</sup> *Essays in Radical Empiricism*, p. 87.

unless the distinction exists there can be no experience at all.

To avoid misunderstanding, it is necessary to state the precise conclusion of this chapter. The first and all-important consideration is that it is the essence of the self to be conscious, and consciousness is not an object, however localised and individualised, but an act of reference to an object, and the aim of the chapter was merely to follow this principle to its logical conclusions. Nearly any one would admit that the body is not the self, if he mean the body as it is known by the external senses, but it is otherwise if he includes the objects of the internal sense in its connotation. He certainly ought to do so, and I submit that, if he desires consistency, there is only one conclusion open to him. All that can be done by way of proof is to analyse the question carefully and in detail, and the distinctions, at all events, are worth drawing, whether or no the conclusion meets with dissent.

There is no question of robbing ourselves, by psychological analysis, of something that clearly belongs to us of right. Our bodies belong to us, but they are not our actual selves. A man may rightly call his appearance his own, since it belongs to himself exclusively, even if it be coveted by others. But although it is his exclusive possession, it is not, therefore, a part of himself, and that is the respect in which it differs most profoundly from experiences. And there is no question of the importance, or even the necessity, of the body to the self. It may be that a self must be embodied, and embodied in a distinct particular organism. That important tenet is quite consistent with the argument of this chapter. We may even agree with Professor James that 'the body is the storm centre, the origin of co-ordinates, the constant place of stress in all the experience train. Everything circles round it, and is felt from

its point of view.'<sup>1</sup> The body is a constant centre of action, it is the constant focus of perception, and organic sensations are the only ones constantly present to us. It is the cause of the subjectivity of our presentations, and thus goes far to differentiate personalities. These considerations are enough to explain the confusion between the self and the body, especially on the intricate points which have been reviewed in this chapter. But to be a cause of subjectivity is not to be a part of the self.

<sup>1</sup> *Essays in Radical Empiricism*, p. 170 n.

## CHAPTER IV

### THE SELF AS FEELING

IN this and the four succeeding chapters I shall deal with a set of questions which are somewhat different from those already discussed. The object of the preceding chapters was principally to clear the ground, and although the part of the general enquiry into which we are entering is, in a way, the amplification and the test of what has previously been said, it also involves questions which have hitherto escaped notice. I have said enough at the close of the second chapter to indicate the general plan and purpose of this part of the subject, and to show why it is necessary to consider in detail the numerous and somewhat perplexing arguments which attempt to prove that the citadel of selfhood consists of some one particular class of experiences. The self, it may be said, is primarily a knower, and all other elements in its composition, if there are any such, are dependent upon its acts of knowledge. According to others, still more numerous, the essence of selfhood is its activity, and the proof of the primacy of will is at the same time an adequate account of the structure of the self. According to a third party the self radiates out from feeling, clings to feeling, exists because of its connection with a fundamental basis of feeling.

There seems to be a consensus of opinion in favour

of one or other of the two latter views, or, possibly, in favour of the two conjointly. Take, for instance, the following passage from Professor Lipps: 'As experience increases,' he says, 'we separate, by gradual stages, what was originally an undivided unity, the content of the world and that of our personality or, more shortly, the world and the self. In this process the contents of direct self-feeling show themselves, more and more prominently, as the specific basis, or the specific kernel, of personality, or the self, and these are the feelings of pleasure or displeasure, of striving or resisting which accompany all other modes of psychical life. Rightly so; for in them is found the direct meeting-point of consciousness with the relations of psychical contents to one another and to the whole life of the soul, with the particular kind and the whole economy of these relations and, more generally, with our own private being, and not merely our peripheral existence. It is to the contents of this self-feeling that the consciousness of constraint belongs, a consciousness which judgments, even mere judgments of perception, carry with them.'<sup>1</sup> For purposes of clearness it is advisable to separate the question of feeling from that of striving, and I shall begin with feeling.

I have already explained the sense in which I propose to use the term feeling, a sense which seems, in different ways, both narrower and broader than that of Professor Lipps. It is narrower because it excludes striving and resistance. It is broader because it includes other feeling elements than those of pleasure and displeasure. Pleasure and displeasure, however, are regarded, not infrequently, as common constituents of all feeling, rather than as the whole stuff of feeling; and no exception need be taken to this view provided that there is sufficient recognition of those neutral states which are neither predom-

<sup>1</sup> *Grundtatsachen des Seelenlebens*, pp. 408-409.

antly pleasant nor predominantly painful. Any kind of excitement, any kind of emotion so far as that is psychical, in a word the whole affective side of consciousness, is best described as feeling.

Although this meaning of the term is in conformity with the best psychological usage, it is hardly necessary to mention the serious ambiguity of the term 'feeling.' Tactual sensations of hardness, smoothness, and the like may be described as feeling, and even this sense of the word is not entirely irrelevant to the present question, since it is connected with some forms of the feeling of constraint. A more important ambiguity is that between bodily and psychical feeling. Even if the argument of the preceding chapter be accepted in the main, a lurking suspicion may still persist in the mind of the reader that the vital feelings are the nucleus of personality. As Jodl says, 'Respiration, alimentation and sex, as well as mobility, refer not merely to complexes of sensations, but are the most primitive, the oldest, the specifically original needs not only of mankind, but also of the organic world in general.'<sup>1</sup> These feelings are the origin of the idea of self, and of its distinction from soulless things. Nor does their importance cease when the earliest stages of development have passed. To feel fresh or tired, to feel well or ill, these surely are primarily feelings of the body, but they, and the moods which they induce, are, as it were, the tonicity of the self, its vital balance. Together they form that general feeling of bodily tone which we call coenaesthesia, a general mass of feeling which, because of its diffused generality, is at once fundamental to selfhood, and difficult to analyse precisely.

There are two moments in this argument, the first being a proof from origin, the second an appeal to introspection, and the second supplements the first by showing that the nucleus of development persists,

<sup>1</sup> *Lehrbuch der Psychologie*, Bd. II. S. 29.

and that the self, as it rises in the scale of development, does not climb over its own corpse. But the second moment of the argument has been met in the preceding chapter, and we must abide by our decision. The importance of these bodily feelings to the sense of continuous personality is not in dispute, and will be more fully illustrated in the sequel. But so far from being the nucleus of selfhood, they are not even parts of the self, and consequently the argument from origin is the only new one which enters in this connection.

The question of the origin of the idea of self, and of its distinction from that which is not a self, is a very intricate one, and is, fortunately, not directly relevant to our present enquiry. While it is necessary to consider the development of the self, it need not be necessary to consider the development of the idea of the self. The process by which men come to understand the meaning of what actually exists, the long series of instructive errors which beset them before they come to adequate comprehension, is fascinating enough, but is only relevant by way of illustration. That the first stage of this development treats the self as the body, and the second as some part of the body; that the soul comes gradually to be regarded as a film, or a vapour, or a shade, and that these unsubstantial beings must drink blood in order to be really alive—these and similar beliefs are matter of history. And the gradual process by which these different stages are reached is full of interest, though accounts of it are speculative. But it is hardly necessary to point out nowadays that an argument *from* origin is, strictly speaking, only an argument *about* origin. It traces the path of development, and development, doubtless, requires some identity and some continuity. But no one can specify in advance the degree of identity and continuity, and it would be as logical to maintain that a chicken is the yolk of an egg because

•

it develops from that nucleus, as that the self is feeling because it develops from feeling. Indeed, as I have already said by implication, the inference in this instance would be still more precarious. If the primitive self *is* feeling, then feeling may constitute a self, and the further question is only that of the precise continuity of the process of development. But all is altered when the question is that of the development of our knowledge of what the self is, and it is surely not absurd to maintain that, blindly groping, we seize on some elements connected with selfhood, and liable to be confused with it, instead of, from the first, discovering and clearly understanding the self as it really is.

The argument from origin, then, is very likely to prove a mere *ignoratio elenchi*, and there is no reason to suppose it otherwise in the present instance. In the previous chapter I have explained the important analogies between bodily feeling and psychical feeling, and it is hardly surprising that these analogies should add considerable strength to this particular argument from origin. Only psychical feeling, however, is really relevant to the issue. It may be that bodily feelings are the chief conditions of psychical mood and temperament, and that the latter are the core of the self. That question will be discussed in due time. For the moment I desire to point out that the argument from origin may derive seeming plausibility from its use of that perplexing word 'feeling' in yet another sense.

Readers of Mr. Bradley know that when he speaks of feeling he means vague, indeterminate, marginal experience, too indefinite to be known or analysed. To the same purpose Croce argues that philosophers have no right to regard feeling as a distinctive part of spirit. 'Feeling, in fact, has been the indeterminate in the history of philosophy, or rather the not yet fully determined, the *half-determined*.'<sup>1</sup> As he

<sup>1</sup> *Philosophy of the Practical*, English translation, p. 25.

explains, with reference to one of the psychological uses of feeling, 'It has happened that, with various times and authors, all the most rudimentary, tenuous and evanescent manifestations of the spirit have been called "feelings," slight intuitions (or sensations as they are called) not yet transformed into perceptions, slight perceptions, slight tendencies and appetites, in fact all that forms, as it were, the base of the life of spirit.'<sup>1</sup> This sense of feeling clearly supports the argument from origin, since development must proceed from the indeterminate to the determinate. But the support is ambiguous. To argue that the self is feeling in the determinate sense, because it arises out of feeling in the indeterminate sense, is an obvious instance of a purely verbal fallacy.

There are none, I suppose, who would draw this inference explicitly, but the nerve of the inference has not been without influence. It is plain, of course, that indeterminate experiences are either indeterminate feelings, endeavours and cognitions, or else that they are too indeterminate to permit any such distinction to be drawn. If the former, there is no reason to hold that the developed self is more distinctively a feeling entity than a willing or a knowing entity. If the latter, the development to the self proceeds *per saltum* without any marked identity or continuity in its stages. That is possible; but it does not help the argument from origin, since it also permits of the interpretation that the self, and not merely the idea of self, may have developed from something which is not a self at all. Indeed, there is only one way in which this argument from the indeterminate supports the belief in the primacy of feeling. If it be true that indeterminate or marginal experiences can be seen by introspection to be qualitatively similar to *developed* feeling, in a sense in which they are not similar to developed conation

<sup>1</sup> *Philosophy of the Practical*, English translation, pp. 22-23.

or cognition, then, at least, the continuity between the original nucleus and feeling is noteworthy; and that, I take it, is Mr. Bradley's opinion. He speaks constantly of the 'felt mass, akin to pleasure and pain.' But must this analysis be true? It is plain that aesthetic feelings, at any rate, are as definite, as developed and as specifically directed as the cognitions or the endeavours correlated with them; and the same is true of love, hate, sympathy and other feelings. Our strongest feelings, perhaps, are connected with organic sensations, but the feelings are not more indeterminate than these sensations themselves. Perhaps, however, it is hopeless to look for agreement when a term may be used in so many distinct senses. All that I can say is that I cannot find any introspective evidence of analogy in this respect.

When it is maintained that psychical feeling is the core of selfhood, the burden of the argument is usually that feeling either is, or is the index to, the only kind of experience which characterises the private and peculiar domain of self. Most of us would admit that our feelings are the most intimately personal of our experiences. We might assent to the theory that our acts of knowledge are but instances of the universal mind thinking within us; we might be driven to the view, albeit reluctantly, that our striving is but the activity of a cosmic force that envelops and impels us, but we should have much greater difficulty in admitting that our feelings are not our very own. The Cosmos may think for us, and act through us, but we feel our own feelings in its despite.

This argument purports to be founded upon a direct analysis of the nature of feeling. Indeed, it implies the theory that feeling is 'subjectively subjective,' to use Hamilton's terms, and it is necessary to consider this analysis with greater care than the earlier sketch permitted. Hamilton's

phrase is lucid, if unattractive, and his discussion of the question is the more pertinent as his general view of the nature of the tripartite division of mind agrees broadly with that of this essay, and his use of the word feeling, although he restricts it to pleasure and pain, comes much closer to ours than some other uses which have been mentioned in this chapter.

Hamilton believes that feeling plays a part in the life of the self which is intermediate between cognition and endeavour. 'The mere cognition leaves us cold and unexcited; the awakened feeling infuses warmth and life into us and our action; it supplies action with an interest, and, without an interest, there is for us no voluntary action possible. Without the intervention of feeling the cognition stands divorced from the conation, and, apart from feeling, all conscious endeavour after anything would be altogether incomprehensible.'<sup>1</sup> But Hamilton 'does not believe that feeling is a kind of reference to an object. 'In the phenomena of Feeling—the phenomena of Pleasure and Pain,—on the contrary, consciousness does not place the mental modification or state [*i.e.* the object] before itself; it does not contemplate it apart—as separate from itself—but is, as it were, fused into one. The peculiarity of Feeling, therefore, is that there is nothing but what is subjectively subjective; there is no object different from self,—no objectification of any mode of self. We are, indeed, able to constitute our states of pain and pleasure into objects of reflection, but in so far as they are objects of reflection, they are not feelings, but only reflex cognitions of feelings.'<sup>2</sup>

It must be admitted that the essential reference to an object is less obvious in the case of feeling than in that of cognition or endeavour. That cognition

<sup>1</sup> *Lectures on Metaphysics*, vol. ii. p. 428. The passage in question is quoted from Biunde, but states Hamilton's own view.

<sup>2</sup> *Ibid.* p. 432.

involves reference to an object goes without saying, and it is equally clear that striving involves an attitude towards an object. Feeling seems on a different plane. It is not an attitude *towards* an object but the way in which the subject is affected by the object. Now if the meaning of this last statement were only that the object *causes* feeling, then it would in the first place be false, and in the second would not prove any *conscious* reference to an object. We may and do experience both grief and joy at the fate of fictitious characters in a novel, and these, in any ordinary sense of the word causation, could not cause anything. Similarly, some totally irrelevant circumstance may be the cause of very real feelings. A teacher may be annoyed with his pupils because he has missed his breakfast, but he is, none the less, really annoyed.

To say, then, that the attitude of feeling is the way in which the subject is affected by an object does not mean that the object causes this feeling but refers to the way in which the subject is consciously affected. It is the receptive attitude of the subject in respect to the object, and therefore would seem to imply reference to the object. Another analysis, however, is possible. To say that the subject is consciously affected in feeling is to say that feeling is the attitude in which the subject is affected when and because he is conscious of an object, and this statement is perfectly compatible with the view that there is direct reference to an object only in cognition and endeavour. To decide between these views on introspective grounds is exceedingly difficult, but there are no other grounds on which the question can be decided. Both theories can account equally well for the part which feeling plays in psychical life. Indeed it might be possible to maintain that feeling, cognition and endeavour are not really distinguishable elements in the life of the self, but only distinguish-

able aspects of a single psychical process. But this theory is only tenable if it is possible for one 'aspect' to predominate, in certain cases and not in others, over another 'aspect.' If, however, the 'three aspect' theory is possible, there is no reason whatever why every aspect should refer directly to an object, even granting that they are all concerned with an object.

I do not say, then, that the interpretation of feeling as a reference to an object can be conclusively proved, but there are reasons for deciding in favour of that view. There are many instances in which it is the best explanation, and none in which there is any good reason to deny its possibility. Pleasure and pain seem at first sight to support Hamilton's analysis. In examining them we frequently fail to find a reference to an object, in any sense which could not be explained on this theory. But there are other instances in which his analysis is, to say the least, forced and unnatural. I have already mentioned the case of aesthetic feelings, and I may mention other instances. If I am pleased with Tony Weller and bored with Mark Tapley, if I love Colonel Newcome and hate his nephew Barnes, I cannot help thinking that my feelings have a direct reference to these gentlemen. There are other cases, certainly, in which this reference is less marked, but none in which it may not be supposed to hold, and in the instances of love, and hate, and desire and many other forms of excitement, this reference is so marked as to be compelling. Yet these are all attitudes of feeling, desire no less than the rest of them. Conclusive proof may be impossible, but the balance of evidence is against Hamilton, not for him. And there are some who not only disagree with Hamilton but find the contradictory of his view to be self-evident. 'Pleasure,' says Husserl,<sup>1</sup> 'is unthinkable without an

<sup>1</sup> *Logische Untersuchungen*, Bd. II. S. 388. Cf. the whole passage.

object in which pleasure is taken . . . and this because the specific nature of pleasure involves the relation to the pleasant object. In the same way the experience of conviction is impossible unless there is something of which we are convinced.'

If, then, feeling be a reference to an object, as other experiences are, it is hard to suppose that it is a private possession in any sense in which they are not. And this conclusion, so far from being paradoxical, is the plain verdict of ordinary reflection. Our acts of knowledge and our acts of will are our own. No one can resolve for us, no one can supply us with understandings. Two men may think of the same thing, but they are not, therefore, identical beings even in respect to that thought. The objects may be the same, but the acts of cognitive reference to them are not the same. I do not see that it is necessary to labour this point. It could not be disputed except by overthrowing the whole analysis of experiences on which this essay proceeds. The more we reflect, the more we come to see the co-ordinate necessity of all three elements of mind. No doubt the fact that all are necessary does not in itself prove that all are equally important, and therefore it is necessary to examine the claims of each of them for predominance. But, so far as the argument has gone, there is no ground for assigning this predominance to feeling, even in respect of its private and particular character. Feeling may be the usual index of such particularity in the self, but it is not, intrinsically, more obviously 'ours' than other experiences. Are not a man's acts of memory, of association, of judgment, as characteristic of him as his feelings? Is not the difference in this respect a fair criterion of the differences of personality? And does not the same account hold good of his efforts, and aims, and endeavours?

It is probable that the sense of 'feeling' which

identifies it with organic sensations (including kinaesthetic sensations) is chiefly responsible for this argument as well as for its predecessor. Husserl, for instance, who denies, as we have seen, that psychical feeling is subjectively subjective, is prepared to admit, in the same passage, that physical feelings probably are. And there is no need to dispute such a theory. Organic sensations are peculiar to the individual subject, and it would be misspent subtlety to argue the point further. Indeed it is clear from the argument of the previous chapter that organic sensations are specially apt to be confused with the self because they are more distinctively subjective than any other sensations. Let it be so. The conclusion is irrelevant to the present question.

The doctrine that the self should be defined by interest is a variant of the same theory, and requires fuller mention than it has received hitherto in this discussion. It is, of course, totally incapable of affording an exact definition of selfhood. The self does not consist merely of interest, however widely that term be employed. There are characteristic experiences which are not interest at all, and if the self be something over and above its experiences, then it is also above and beyond that particular class of experiences which we call interest. Similarly many things in which we are interested are by no means parts of ourselves. If Torquemada was interested in his victims, his interest would have been rather different had they been parts of himself. It may be argued, however, that if we speak of an object as ours we mean, unless we are lawyers, that it interests us. One man directs his attention to poetry, another to philosophy, a third to engineering. Each makes these objects his own, and the reason is that these different things appeal to him in a special sense. His individual preferences are the root of his selection, and the nature of the self is best seen in the things

it selects. Because the self is revealed in its selection, its most distinctive element is that which determines this selection.

The contention may be true enough, but it fails to prove the point in dispute. Feeling is the way in which the subject is affected by the objects presented to him, and this, in its turn, determines his reactions towards them. But the reactions themselves are just as characteristic of the self as its feelings, and neither is more characteristic than the cognition which guides and informs them both. King Lear loved Goneril and Regan when he divided his kingdom between them, and he was offended with Cordelia. His feelings and his actions were both characteristic of the man, but not less characteristic was his lack of foresight and wisdom. He was old and venerable, but very far from wise. When he knew more he loved Cordelia only. Feeling is not the only relevant feature of the case, it is symptomatic of the degree of a man's knowledge of the nature of the object which excites it. Feeling and interest may, and do, indicate a special relation to the self, but any other of the principal classes of experiences might serve this purpose equally well.

Finally, in this connection, we may mention the argument that we find ourselves as we really are in those more prolonged trains of feeling which are called moods. There are certain moods in which we sink within ourselves to the neglect of the outside-world. We are aware of the voice of the singer, the strains of the accompaniment, the hall, the audience. But these things seem to drag us from ourselves. They are less to us than the private internal mood of mere enjoyment, and that is where we should look for the essence of the self. When we are released from the tyranny of the world, and from the efforts and attention it requires of us, we become ourselves, and it is clear that in these cases the mood itself

determines the chain of thoughts, associations and desires, even if these moods are more than half compact of bodily feeling. So runs the argument; and I do not wish to renew the discussion whether feeling, or trains of feeling, are, in an unusual degree, private and particular. I have tried to show reasons to the contrary, but let us grant their insufficiency. Even if feelings are distinctively private and particular, it does not follow that they are the most fundamental parts of the self. That would only be the right conclusion if the self is real precisely in proportion as it can detach itself from all else and creep within its own shell, and this is not the true account of human personality. Are the men whose lives radiate out towards other things and other persons less really selves than those who try to shrink into some unapproachable crevice of private being? Surely the facts are otherwise. To understand the self it is best to go outside it and consider its influence and the range of things which it contemplates. To argue that these ought not to count, or ought not to count very much, is like arguing that the most essential parts of a lighthouse are those which are not constructed for the diffusion of light.

It remains to consider the most important argument of all, and that is found in Mr. Bradley's illuminating discussion of the meanings and the reality of self.<sup>1</sup> No two chapters have done more, or are likely to do more, towards unveiling the obscurity of the subject than these. Their interest and their value have compelled attention to the problem, and neither the interest nor the value is lessened by the fact that the theory does not commend itself to every one. It is therefore in no spirit of mere contentiousness that I should like to give some reasons for dissenting from Mr. Bradley's conclusions.

The principal merit of Mr. Bradley's analysis is

<sup>1</sup> *Appearance and Reality*, Bk I. chapters ix. and x.

that he insists on a precise answer to a precise question. 'The fact of one's own existence, in some sense, is quite beyond doubt.'<sup>1</sup> But in what sense precisely? And he distinguishes a number of meanings, most of which are inadequate.

The self cannot be the body, in any ordinary sense of these words; and its essence can never be discovered by the mere consideration of 'the total filling of the man's soul at this or that moment.' This, of course, must be admitted, but such inspection need not be so valueless as Mr. Bradley supposes. For in this inspection we may distinguish psychical acts of reference from the objects to which they refer, and may restrict our further enquiry to these acts alone. Such a mode of procedure, however, would be impossible for Mr. Bradley. He would refuse to draw the distinction in this sense, or to regard the acts as mental and the objects as non-mental. It is self-evident to him that nothing can exist except Experience, and he interprets this as meaning that act and object cannot be considered distinct existences, but only moments in a whole.

But although Mr. Bradley rejects such an analysis, he eventually arrives at something similar. His reasons for doing so, however, depend upon the rejection of certain other possibilities, and it is necessary to consider his reasons for that rejection. Since the self is a continuous unity, he argues that it is impossible to discover its essence by analysis of any given state, and that there is no constant average mass of experience which deserves to be called the essence of the self because it alone is present in its totality at any given moment of the existence of that self. This type of problem will occupy us later. At the moment it is enough to assent to Mr. Bradley's argument that any such constant average remaining identical 'from the cradle to the coffin' would be

<sup>1</sup> *Appearance and Reality*, p. 76.

such a pitiful residuum that no one could dare to call it a self. And in the same way there is no inner nucleus of coenacsthesia, or the like, which is more than a wretched fraction or a poor atom. Nor does the supposition of a monadic pure ego appreciably alter the case. 'If the monad stands aloof, either with no character at all or a private character apart, then it may be a fine thing in itself, but it is mere mockery to call it the self of a man.'<sup>1</sup> Nor should the self be defined as that in which interest is felt.

Mr. Bradley argues that if these theories are rejected, the problem must be regarded in a different light, and the proceeding which promises best is the distinction between subject and object, between self and not-self. This relation is either theoretical or practical: theoretical in the case of perception or intelligence, practical in that of desire or will. Mr. Bradley, then, after a process of elimination, seems driven to attack the problem on the lines we adopted in our second chapter, and the chief difference, it might seem, is that he has refused to include feeling, in any sense, among the experiences which refer to an object. We shall find, however, that his analysis differs radically from ours, and that he maintains that feeling, in his sense, not in ours, is the sole constituent of the subject side of the subject-object relation.

In any given case, Mr. Bradley proceeds, both of the terms which enter into the subject-object relation have definite contents. But when we consider either term we cannot say that it is such that it must invariably be subject or invariably object. Thus we have reason to believe that the subject-term can always be made an object, or, at least, we cannot specify the exceptions and we know them to be few. The most intimate features of the subject-term at any given moment may be set before the self at any other

<sup>1</sup> *Appearance and Reality*, p. 87.

moment, may be considered as object, and so become part of the not-self at that moment. The same account holds of desire and volition. 'As introspection discloses this or that feature in ourselves, can we not wish that it were otherwise? May not everything that we find within us be felt as a limit and as a not-self, against which we either do, or conceivably might, react?'<sup>1</sup> And a similar argument holds of the object part of the relation. There is nothing in the object which cannot become part of the subject, or if there is anything, it is so trivial and unimportant that it may, for practical purposes, be neglected. When I direct my attention to some object I do not straightway pass out of all relation to the object I attended to a moment before. What happens is that this object ceases to be an object and becomes part of the self. It passes into a general background of feeling from which it was detached as an explicit object, and to which it returns. 'And the fact of the matter seems this. The whole psychological mass, which fills the soul at any moment, is the self so far as this mass is only felt. So far, that is, as the mass is given together in one whole, and not divisible from the group which is especially connected with pleasure and pain, this entire whole is felt as self. But, on the other side, elements of content are distinguished from the mass, which therefore is, so far, the background against which perception takes place. But this relation of not-self to self does not destroy the old entire self. This is still the whole mass inside which the distinction and the relation falls.'<sup>2</sup>

It is clear that the meaning which Mr. Bradley attaches both to subject-term and to object-term is so fundamentally distinct from ours that a whole treatise on epistemology would be required to make thorough discussion possible. To speak of the object of know-

<sup>1</sup> *Appearance and Reality*, p. 91.

<sup>2</sup> *Ibid.* p. 95.

ledge or will as a content which is now rendered explicit and opposed to the self, and anon becomes implicit and part of a felt mass akin to pleasure and pain, is to speak an entirely different language from that which has hitherto been employed in this essay. Any criticism, therefore, is bound to appear inept, and yet Mr. Bradley's theory is much too important to be passed over.

But is it not clear that we know the self too intimately for Mr. Bradley's view to be true? Let us consider our knowledge or our volitions at any particular moment. Is it an adequate analysis of either of these processes to say that a felt mass, akin to pleasure and pain, is somehow confronted with, or opposed to, an object? How can we say that feeling knows or that feeling wills, and how can we avoid saying that the self knows and that the self wills? It is true that Mr. Bradley, to be consistent, is precluded from telling us what feeling means. For if he could regard it as an object, he would drag it from its background, and the shock would be fatal. All we can know about it is that it is, and that it is indissolubly connected with pleasure and pain. Surely much of the task of psychology consists in analysing the different characteristics of knowing, willing and the like, and this from the point of view of the subject, not of the object. We know more than a background of feeling. We know psychology.

To such an argument Mr. Bradley has a very obvious reply. 'These arguments,' he might say, 'only refute mine by ignoring my meaning. We know too much about the self to say that it is but a mass of feeling at any given moment. How? By introspective analysis, and by that only. But my argument was that introspection is a kind of knowledge or perception. It is therefore aware of an object or not-self, and from this doom it cannot escape. Hence the objection is futile. The self is never an object.'

We have already answered this by implication. Acts of knowledge or acts of will are not primarily objects. They are primarily references to an object. To use Professor Alexander's terminology, they are primarily enjoyed and not contemplated. It is false, however, to maintain that they can never be contemplated.<sup>1</sup> Introspection is just this contemplation, and, as we have already argued, there is no good reason for denying that introspection may succeed, *i.e.* that we may discover by introspection what experiences are in themselves. Certainly we may be mistaken about our experiences. Cognition is no more infallible in this respect than in any other. Everything is what it is, and is not some other thing. Similarly, experiences are what they are, and are nothing else. But we may fail to understand what experiences are, just as we may be unable to understand what other things are. Cognition of an experience is as liable to error as any other cognition. The whole question at issue is whether the object of cognition must be only an appearance. That is part of Mr. Bradley's metaphysics, and his metaphysical system may be true for all we have shown to the contrary. But if it is permissible to neglect these ultimate points of epistemology (and they do not enter into the discussion at the level at which Mr. Bradley conducts it in this place), we are entitled to maintain that when we consider the self as an object we are really considering *it*, and that acts of cognition when introspectively examined have distinct features and are not sunk in a mass of feeling, much less constituted by that mass. Indeed, it may very well be maintained that the introspective awareness of experiences is less likely to deal with mere appearance than, let us say, sense-perception is. Why should not these experiences be real parts of mind as it is in itself?

The question is one of introspection, and, in the

<sup>1</sup> As Professor Alexander does.

last resort, of introspection only. It is agreed that there is always some content of mind other than the objects before it at any given time, but Mr. Bradley maintains that this content cannot be explicitly contemplated, or coherently described and analysed. It is true that an experience *in vacuo* is unthinkable. Every experience is united to its specific object, and would not be an experience unless it were so united; but that does not affect the question of the nature of the experience when it is united to its object. Our argument has been that the contents of mind can be discovered by introspection, and can then be seen to be determinate. In that case the self cannot be mere feeling in Mr. Bradley's sense; and, plainly, it is not mere feeling in any other sense.

## CHAPTER V

### THE SELF AS WILL

THE arguments in favour of the primacy of will are so varied and important that they require what may seem a disproportionate amount of space to be adequately treated. Indeed, they might very well have a whole volume devoted to them. In default of this, it will conduce to clearness if the subject is subdivided, and I propose to devote three separate chapters to its discussion. The first of these will be psychological in the main. The question, 'If the self is essentially will, what are the experiences involved?' seems to me a prerequisite of any further enquiry. It will form the subject of this chapter, together with questions of interpretation which arise immediately and directly from it. In the second of these chapters I shall consider the various meanings of purpose. Perhaps the self should be defined as purposive, and, in any case, it will be found that purpose and its implications are the chief warrant for maintaining, rightly or wrongly, that the self is will. The third chapter will deal with what, for want of a better name, may be called 'The Primacy of the Practical Reason.' It will refer to certain metaphysical arguments which have been prominent in the history of philosophy.

To assert that the will is the essence of the self is as familiar to Common Sense as it is to philosophers.

It is enough to give an illustration from that kindest of works, Sir Walter Scott's *Journal*: 'A touch of the *morbus eruditorum*. . . . Fighting with this fiend is not always the best way to conquer him. I have always found exercise and the open air better than reasoning. But such weather as is now without doors does not encourage *la petite guerre*, so we must give him battle in form, by letting both mind and body know that, supposing one the House of Commons and the other the House of Peers, my will is sovereign over both.'<sup>1</sup> Truly, Sir Walter was an example of the predominance of will, if ever there was one, and not the less so at the period when he wrote these words. For it was then that he faced ruin boldly, and gave her the noblest of battles. It is natural to believe that the will is sovereign. It is not unusual to deny that its monarchy is limited.

A word of explanation is necessary with regard to terminology. Hitherto I have used the word 'endeavour' or, more rarely, 'conation' to express the genus of psychical facts which fall for discussion here, and these, on the whole, are the best expressions for describing the active side of human consciousness. 'Will,' strictly speaking, has a narrower denotation. It should mean volition or voluntary action. It implies conscious consent or resolve, and not only are many human actions involuntary or non-voluntary, but much seeking and striving lacks the specifically volitional element of resolve. This strict usage is, without a doubt, the correct one, but there is a broader usage in which the word 'will' is used to include, not only volition, but also any sort of endeavour or conation. The ambiguity is not usually very serious, and it is so firmly rooted that it requires at least lip service. I used the word 'will' in the broadest sense when I selected the title of this chapter, but I intend to give

<sup>1</sup> Pp. 45, 46.

it that broad signification as seldom as possible, and, in the sequel, to distinguish it carefully from the other 'active' experiences which are relevant to this discussion.

The concept of mental activity has probably excited more heated discussion among modern psychologists than any other. To some it is a 'scandal,' and to others merely an obvious fact. But even the acerbity of the discussion has some redeeming features: it has forced the issue into relief, and has begotten much searching and valuable analysis. 'Perhaps the most elaborate work ever done in descriptive psychology has been the analysis by various recent writers of the more complex activity situations.'<sup>1</sup> Accordingly it is difficult, if not impossible, to say anything both new and important on the question, and I cannot hope, nor do I wish, to do more than cover the ground already traversed by others. But the question must be discussed in any serious attempt to grapple with the problems of the present essay or the present chapter. And therefore it must be faced now.

There are three questions which excel all others in importance, from this point of view. The first is, 'In what respects are certain experiences called active, and what are these experiences?' In other words we must try to discover and to analyse the active elements of consciousness. And this might seem the sole aim of the present section. But a little reflection will show that two other questions are forced upon us. It is necessary to ask not only what experiences are called active but whether they are rightly so called. Do we *mean* anything by calling them active and, if we do, can our meaning be intelligently expressed? It is here that the 'scandal,' if there is one, shows its ugly head. No one can reasonably object to analysis, but the explanation of

<sup>1</sup> James, *Essays on Radical Empiricism*, p. 163. The reader will frequently perceive my debt to this essay on the Experience of Activity.

the analysis is quite a different matter, and the critics cry out in horror, not because there has been analysis, but because that analysis, though susceptible of divers interpretations, is straightway regarded as an oracle. We must, therefore, define our position in this respect also. And in the third place we must endeavour to discriminate as accurately as possible the various subdivisions of the genus 'active experiences.' For when it is said that the self is primarily will, the word 'will' is often used ambiguously, and it is impossible to conduct any argument until the meaning of the terms employed is made explicit.

(1) The plain man would say that wherever anything happens, wherever change takes place, wherever there is anything *doing*, any life or any process, there activity in some sense is implied. But in saying so he certainly would not mean that every process and every change, just because it is a process or change, is necessarily active. He would recognise that some processes are active and others passive, and consequently his assertion would only mean that the existence of any process or change indicates the presence of something active somewhere. A man is drugged and murdered. *He* is not active, but the opiate and the murderer are. We can infer the presence of some activity somewhere from the events which happen in the most passive subject.

Now when activity is regarded as an aspect of, or element in, experience, it is clear that there is reference to those facts in which activity, in the plain man's sense, is somehow involved. There may be disputes concerning the ultimate meaning of the term, but the fact of the presence of change and process in psychical life is beyond all cavil. Every act of consciousness is a process, and the totality of these processes, as seen in the life of the self, flows ceaselessly through time. More than that: this change is experienced, and is not merely an inference. We

may infer change from the knowledge that one and the same thing has occupied different positions or possessed different qualities at different times. But we may also perceive a body moving, or changing, and such changes are directly perceived, not merely inferred. There is a clear difference in the two cases, and it is only because change can be perceived in some instances that it can be inferred in others. Similarly we may merely infer a change in our psychical lives. A lover, meeting his mistress after an interval of time, may be surprised that she no longer attracts him, although she is, to all appearance, the same as she was, and so he may infer that he himself has changed. But he may also perceive conscious process going on, he may directly experience change in himself, and therefore change, directly perceived, is an important and distinctive feature of mind.

This, however, is a very small step in analysis. The perception of mental process indicates that there is activity somewhere, but the activity, so far as the analysis goes, need not even be mental. The experiences in question might merely be passive, as many experiences are. It is necessary, therefore, to distinguish those perceived psychical processes which are active, from others which are passive or, like cognition, are neither active nor passive. Activity experiences are only one class of experiences. That is clear to introspection, and no other evidence is relevant. Some experiences feel active and others passive, whether or not it is possible to define the meaning of activity or passivity precisely. Let us ask, then, whether it is possible to give an intelligible account of the experiences which we call active. The *term* activity may be a misnomer, but the *experiences* are real and can, perhaps, be analysed.

There are certain concepts which may be employed for the description of activity experiences, and the chief of these are direction, initiation and immanent

causation or, as Mr. Bradley puts it, self-caused change. It is plain that these notions are, at least, relevant. Without the concept of direction activity would be meaningless. When we seek anything, strive after it, aim at or intend it, the very being of these processes is to be in some direction. This is more than the fact that all conation must be guided by some cognition, that *ignoti nulla cupido*, that there is always some awareness of the end. It means that the being of conation is to seek—something. It is, being directed. This, then, is a fundamental characteristic of activity experiences, but it is hardly sufficient to distinguish them. After all, every reference to an object is directed towards that object. It is the manner of the direction that counts. And the manner of the direction in the present case is just to seek or strive.

In particular, it is not enough to say that the *differentia* of conation consists in the fact that 'the stream of consciousness feels its own current,'<sup>1</sup> that it 'is, *eo ipso*, *experienced* transition,'<sup>2</sup> or the like. To feel oneself moving, even in a certain direction, is not to feel active, and is not enough for activity. When the crew of a sinking ship experience a transition into the waters, they are not experiencing an active transition, and although the analogy of the stream may be useful, it also is insufficient. A stream has a source and it flows towards the sea, but it does not seek the sea, and it would not seek it even if, *per impossibile*, it were aware of its own current. It is possible to experience transition in a certain direction without any implication of conscious activity. The obsession of an *idée fixe* would tally exactly with the description. And we must be prepared to face the possibility that no description will really suffice, and that seeking is nothing but seeking. But descriptions,

<sup>1</sup> Stout, *Analytic Psychology*, vol. i. p. 160.

<sup>2</sup> *Ibid.* p. 159.

none the less, have their value, and so the quest should not be abandoned at once.

Let us turn to the concept of immanent causation, with the proviso already mentioned, *i.e.* that the concept is regarded as nothing but a description of the *differentia* of activity experiences as they appear to introspection. Activity, perhaps, means self-caused change, and if, to return to the metaphor of the stream, we regard its current as driven by its own momentum, then it may be right to maintain that this sort of experienced transition is mental activity.

It is clear, as Professor Stout has argued,<sup>1</sup> that mental activity is, in one sense of the words, not merely immanent. Seeking and striving are active experiences, but they may, and usually do, involve a constant reference to external conditions, a constant conflict with obstacles which restrain, and a constant striving for a goal which is sought by the process but need not form any part of it. A man, for instance, may seek distinction among his fellows. It is they, and not he, who can accord this distinction, and their existence, their aims, their very whims and caprices, are the constant conditions of his striving. If immanent is used as the contrary of transient, and this is how it ought to be used, then it is clear that activity experiences are not really immanent. It is unnecessary to add that activity experiences have little in common with the momentum or the inertia of a particle.

The concept of immanence, however, is used in another sense when it is applied to psychical activity. It does not deny the forward or the outward reference of activity experiences. What it does mean to deny is causation *a tergo*. It is meant to be synonymous with self-initiation, and that is our meaning when, for instance, we speak of the freedom of the will, or distinguish activity from passivity. A process which

<sup>1</sup> *Analytic Psychology*, Book II. chap. i.

initiates, or seems to initiate, will be called active, a process which depends upon the initiation of something else will be called passive. Thus we may resolve to remember something which we have forgotten, and, for that purpose, give rein to the play of association in the fond hope that something will turn up to give us the clue we want. Only the experience which initiates, in this instance the resolve, is an activity experience. The rest depend upon it.

This feature, characteristic of activity experiences, has been variously described as spontaneity or indetermination, and, of course, appears to involve all the difficulties attaching to the freedom of the will, the adequacy of mechanism to account for bodily behaviour, and the like. But these difficulties need not disturb us at present. The question at issue now is merely one of introspection. Do we find this apparent feature of initiation when we introspect, and, if so, is it a characteristic common and peculiar to activity experiences? The answer to this question is that activity is a characteristic of any experience which is called active. There is no mystery about the matter. We *begin* processes. We make fresh starts. And even if we repeat what we have done before we need not repeat it in a mechanical fashion. We may begin it again. The process does not roll on pushed by some extraneous impulse. We start it afresh. We make up our minds, give it our *fiat*, say 'let it be done.' Here there is activity and initiation. And such experiences feel quite different from those which ensue upon them.

Initiation, then, is a fact which demands recognition, and is characteristic of some experiences and not of others. The pity is that its reality to introspection, and its precise meaning for introspection, have been obscured by the introduction of irrelevant considerations. I may refer briefly to two such obscurities. In the first place, the presence or absence of repetition

is irrelevant. Repetition is not necessarily unspiritual. Spirit, like other beings, may never repeat itself exactly, but would it be spirit if it never repeated itself at all? The fundamental fact is that we may begin again, and that when we begin again we really begin, even when and so far as there is repetition. If a Cabinet Minister resolves to bring in a bill, in precisely the form in which he introduced it before, the fact of repetition need not make any difference to his responsibility or his initiation. In the second place, initiation does not imply a rupture of connection with the past. It is, of course, compatible with the introspective evidence that the real and complete cause of an act of initiation may be the brain or the subconscious. These are not revealed to introspection, and consequently are irrelevant. But the more important point is that initiation is not mere immanence, and does not imply discontinuity with those previous events which are so revealed.

Now, whether it be  
 Bestial oblivion, or some craven scruple  
 Of thinking too precisely on the event,  
 A thought which, quarter'd, hath but one part wisdom  
 And ever three parts coward, I do not know  
 Why yet I live to say 'This thing's to do';  
 Sith I have cause, and will, and strength, and means  
 To do't. Examples gross as earth exhort me.

Had Hamlet acted according to these exhortations, had his too precise thinking borne fruit in deeds, there is surely no question that his resolve would have been connected with those thoughts and exhortations. And there is just as little question that he did not undertake this initiation of action, which is surely a proof that the initiation of action is not identical with the motives towards it which throng into the mind. Initiation is compatible with continuity, and does not arise *ex nihilo*. It is the moment of birth in the soul, and birth is a fresh start, rooted in the past.

We may fairly claim, then, that this characteristic of initiation is *common* to all activity experiences. It may be most obvious in resolve, but is also true of all seeking or striving whether they involve conscious resolve or not. But it is not peculiar to activity experiences. It holds of adynamic experiences as well as of dynamic, it is as marked a characteristic of the assent of judgment as of the consent of will, and that is why the two are often confounded, as in Descartes's theory of truth and error. If this initiation be the meaning of freedom, then the freedom of judgment is as important and as unmistakable as the freedom of will, and yet the two are not identical. Accordingly, the *differentia* of activity experiences is still to seek, although some of their indispensable characteristics have been discovered. Seeking, striving, choosing, and the like, are the only activity experiences proper. They alone are dynamic without being passive, and the array of descriptive concepts we have mustered in the attempt to analyse activity apply to certain adynamic experiences also. Nothing except introspection can gauge the unanalysable residuum.

This may seem a very meagre answer to our first question, but meagre as it is, it is sometimes disputed on psychological grounds. It will be well to notice some of the more important of these objections before proceeding to the second, and much more difficult, question of interpretation. The first objection is familiar to all students of Berkeley.<sup>1</sup> 'Such is the nature of Spirit or that which acts, that it cannot be of itself perceived, but only by the effects which it produceth. If any man shall doubt of the truth of what is here delivered, let him but reflect and try if he can frame the idea of any power or active being. . . . So far as I can see the words will, understanding, mind, soul, spirit do not stand for different ideas, or in

<sup>1</sup> *Principles*, § 27.

truth for any idea at all, but for something which is very different from ideas, and which, being an agent, cannot be like unto, or represented by, any idea whatsoever.' But Berkeley speedily saw that his position required modification, and in the second edition of his book he set to work to amend it. Though we have not an idea (*i.e.* a presentation) of soul, spirit or the operations of the mind, we have a 'notion' of them 'inasmuch as we know or understand the meaning of these words.' These operations may be called 'things' or 'beings,' though not ideas. In our own case we comprehend them by 'inward feeling or reflection'; their existence in other minds is matter for inference. And he seems to give the case away in the Dialogues between Hylas and Philonous.<sup>1</sup> 'My own mind and my own ideas I have an immediate knowledge of; and, by the help of these, do mediately apprehend the possibility of the existence of other spirits and ideas.' This cognition, he further informs us, is cognition 'by a reflex act.'

In its broad issues Berkeley's original position was simply the denial of the possibility of direct introspection, and as this view has already been considered more than once, it need not be considered again. Berkeley's special reason for maintaining his view, however, is (at least in form) somewhat different from Comte's. According to Berkeley an idea is the object of knowledge and is passive, and any possible object of knowledge is passive. But activity, *ex vi terminorum*, is active and therefore no active experience, *qua* active, can ever be the object of knowledge. But this analysis is fundamentally mistaken. Ideas of sense are perhaps passive since they come from a foreign source and bear the marks of their origin with them. But neither activity nor passivity play any part in the analysis of knowledge or perception. Knowledge is aware of its object, and this

<sup>1</sup> Dialogue III., Fraser's 4 vol. edition, vol. i. p. 448.

•

awareness is neither active nor passive although activity of some sort and passivity of some sort may be implied among the conditions of the existence of knowledge. Accordingly, Berkeley's difficulty is entirely manufactured, and he has not even succeeded in establishing a presumption in favour of the view that the activity element in experience is opaque to introspection. The object of knowledge need not be passive, and therefore there need not be any contradiction in knowing an active experience as active. If such a contradiction existed it would also be fatal to Berkeley's 'notions.'

It must be admitted, however, that many of the 'effects which it produces' are often erroneously ascribed to the concept of activity itself. When strain, *e.g.*, is said to be a feature of activity there is an example of this confusion. Strain is essentially a sensation, and so, it seems to me, is effort. They are *qualia* of the conflict between the activity and the obstruction it encounters. Similarly the feeling of release from strain is also a sensation. It is not activity itself. These sensations are bodily, and this fact introduces a very real difficulty into the analysis. In the main there is no greater difficulty in distinguishing active experiences from collateral bodily accompaniments than in distinguishing assent or denial from a nod or a shake of the head. But in some cases the difficulty is considerable. It is often difficult, for instance, to distinguish psychical activity from the sense of unconstrained bodily movement. The reason for this is, I think, that our seeking and striving is usually directed towards change in the physical world and our bodies are our only constant instruments for effecting such change. And from this point of view it is true to say, as Professor James does in a passage which I have already quoted in part,<sup>1</sup> that 'the body is the storm centre, the origin of

<sup>1</sup> *Essays in Radical Empiricism*, p. 170.

co-ordinates, the constant place of stress in all that experience-train. Everything circles round it and is felt from its point of view. The word "I," then, is primarily a noun of position, just like "this" and "here." Activities attached to "this" position have prerogative emphasis, and, if activities have feelings, must be felt in a peculiar way.' But it is false in fact that the body is invariably a centre of this sort. When a man sets himself to think out a problem in ethics, how is his body the centre of his action? We can choose to do and strive to do things in which bodily movements have no place or, at any rate, no conscious place. And if we reflect carefully we shall find that the activity characteristics of choice or striving are in no way affected thereby. Hence the bodily sensations are only collateral accompaniments of activity and are not parts of its essence.

A second objection takes the form of saying that introspection, carefully performed, shows no trace of any distinctive class of activity experiences. Thus, according to Professor Münsterberg,<sup>1</sup> 'a special collection of sensations is just what we call will.' We find in every volition that 'the clear consciousness of a certain presentation  $\alpha$  is preceded by another state of consciousness which contains the presentation  $\alpha$  as part of its content.'<sup>2</sup> This view, Münsterberg contends, is inevitable because the alternative view of an *Innervationsgefühl* can be proved to be worthless. And that would be true if there were no other alternative. There is no good evidence for the *Innervationsgefühl*. James and Münsterberg have slain it.<sup>3</sup>

Münsterberg's analysis would have been still more convincing had he expressed it thus: 'In every

<sup>1</sup> *Die Willenshandlung*, S. 96. The account in the author's *Grundzüge* is different.

<sup>2</sup> *Ibid.* p. 97.

<sup>3</sup> See Münsterberg, *ibid. passim*; and James, *Principles of Psychology*, vol. II, pp. 494 ff.

instance of will the expectation, clear or obscure, of the possession of a certain object, or of the actual experience of a certain sort of bodily sensation, invariably precedes that possession or that actual sensation. 'This fact of expectation, which may be erroneous, together with our experience of the continuity of the transition in the cases in which it is not erroneous, is all that we mean by will.' And he would add one further requisite. There must be a connection with our own bodies, and the presentation of *their* successive phases must be the perceived link between foretaste and reality.

There are other variants of a similar doctrine. The theory of ideo-motor action, for instance, is one of them. It, too, denies that there are any specific experiences of striving or willing. We think of rising from bed in the morning, and lo! we have begun to dress, without knowing why or how. That is the whole psychology of the matter. Striving is analysed away. It is a blend of two factors, (1) the expectation of the result of certain processes due to previous experience or, perhaps, merely the thought of this result, and (2) a preference or liking for the result. And sometimes the irrelevant remark is added that seeking or striving cannot be an original element. We cannot want anything without knowing that we like it, and without supposing that we have a chance of getting it, all of which presupposes previous experience. This contention may, or may not, be true, and it is very often disputed, but it is clearly impotent to prove that striving is not *now* a distinctive element of consciousness.

If the appeal be to introspection, then to introspection let us go. Is it really possible to explain away the experiences of seeking, endeavour, or resolve in Münsterberg's fashion, or in any similar fashion? Surely the analysis omits an essential point. Do we not all drift frequently into situations

which we anticipate with pleasure and yet do not actively seek after? In these cases all the elements of Munsterberg's analysis enter, and yet there is no seeking. I have already said a good deal in illustration of this point, and shall have something to say at the close of the chapter, so further reiteration is useless. The experience of endeavour may be too ultimate to be adequately described, but at least it contains elements which are ignored in this description.

(2) Let us pass to our second question. There are activity experiences. We can point them out if we cannot describe them completely. But are they really active? Do they really *do* anything, and, if so, what do they do, and how do they do it? May not the real agent in the case be something behind the so-called activity experiences, just as a feeling of freedom may be due to an absence of tension? Are the experiences to be taken at their face-value? And what precisely does this face-value mean? These are much more difficult questions, but it is impossible to ignore them.

They may be asked in a sense which is absurd and in a sense which is legitimate. If the question be, 'How does doing do?' or 'how does pulling pull?' it is certainly absurd. To ask how pulling pulls is to ask for a precise analysis of the process of pulling. Otherwise it is mere nonsense. But the question may be put in a form which is legitimate. It is legitimate to ask whether these activity experiences are causes, and, if so, what they cause. And it is also legitimate to ask whether they are causes in some sense in which other experiences are not. Let us address ourselves to these questions.

The problem of the meaning of causation is one of the most intricate, and one of the most disputed in metaphysics. For our present purposes it is enough to distinguish some of its principal interpretations. According to some authors the only

intelligible meaning of causality is that it states a rule of the succession of events in time so that inference from one set of events to another set of events is possible. It is a principle of calculation (not merely of prediction) and it means nothing more. Nor is it used in any other sense in the sciences, *e.g.* in dynamics. But many would contend that this doctrine robs causation of its real meaning. Causation must mean something more in order to be intelligible, and this additional element of meaning is sought in various directions. The principal attempts of this kind are two in number. The first seeks to connect causation with ground and consequence, the second appeals to the very experiences which we are now considering. Activity, on the second view, is something more ultimate than causation. We experience it in the self, and extend it by analogy or 'project' it into our conceptions of causation in other things. We may begin by considering Hume's famous objection to this latter contention.

'It may be pretended,'<sup>1</sup> he says, 'that the resistance which we meet with in bodies, obliging us frequently to exert our force and call up all our power, this gives us the idea of force and power. It is this *nisus*, or strong endeavour, of which we are conscious that is the original impression from which this idea is copied. But, first, we attribute power to a vast number of objects, where we never can suppose this resistance, or exertion of force to take place. . . . Secondly, this sentiment of an endeavour to overcome resistance has no known connection with any event: what follows it we know by experience but could not know it *a priori*. It must, however, be confessed that the animal *nisus* which we experience, though it can afford no accurate precise idea of power, enters very much into that vulgar, inaccurate idea, which is formed of it.' And Hume also objects to

<sup>1</sup> *Enquiry*, Selby-Bigge's edition, footnote p 67.

the argument that we have an intuition of power in the case of voluntary action or, in other words, that we have only to raise an arm to understand causation, and so to refute the most astute dialectician.<sup>1</sup> 'We learn from anatomy that the immediate object of power in voluntary motion, is not the member itself which is moved, but certain muscles, and nerves, and animal spirits, and, perhaps, something still more minute and more unknown, through which the motion is successively propagated, ere it can reach the member itself whose motion is the immediate object of volition.'

In his more elaborate discussion of causation in the *Treatise* Hume remarks that 'the terms of efficacy, agency, power, force, energy, necessity, connexion and productive quality are all nearly synonymous,'<sup>2</sup> and he proceeds throughout on this assumption. If so, the first of his arguments is fully justified, and time has given it clearer proof. Dynamics, for instance, does not require the idea of force, although there are comparatively few who would deny that it employs the idea of cause. But we cannot suppose that the experience of acting freely or of being constrained is in any way applicable to the behaviour of a particle. On the other hand, 'force,' 'power' and 'efficacy,' as usually understood, imply something analogous to this psychological experience of activity. Connection, correlation, causation as applied in dynamics do not. If, then, Hume insists on interpreting the former set of terms as equivalent to the latter, his criticism is justified, and it has clearly an important bearing on the question. The specific features of the animal *nisus* would be irrelevant to the general question of cause.

Again, there is considerable value in Hume's contention that the effects of striving are known only through experience, and have no more *a priori*

<sup>1</sup> *Enquiry*, Selby-Bigge's edition, p. 66

<sup>2</sup> *Treatise*, Selby-Bigge's edition, p. 157

evidence about them than any other kind of cause. His general position, of course, is that there is never any *a priori* evidence for particular causal laws. We find out by experience that bread nourishes, that morphia depraves, that a combination of two poisons results in common salt. Such knowledge depends upon observation. The principle of ground and consequent is helpless. The effects of any substance cannot be deduced from the qualities of the substance until experience has shown what effects the substance works. These effects may be strange and unnatural: they may seem, in the end, a standing miracle, even when we know what does in fact result. In causal laws there is the mere brute fact of regular occurrence. There is nothing like intelligible connection.

It is usual to reply to this that when striving and seeking is a cause there is an intelligible connection with the effect, that striving and seeking are therefore causes *par excellence*, and that any other kind of cause differs from them at its peril. We strive after an end and attain it; we wish, for instance, to visit Florence and we go there. Surely in these cases there is an intelligible connection. The end for which we strive is present throughout: it craves completion, and it receives this completion when the process is fulfilled. But even granting that there sometimes seems an intelligible connection of this sort, there are negative instances in plenty. We try to be healthy and succeed in becoming so. But is the seeking the cause of the result? On the contrary, its success depends upon the observance of the ordinary rules of health, and these are proved, if they are proved, by the collected and compared observations of physicians. Or, again, no one can, by taking thought, add a cubit to his stature, though some try, and no one has volitional control over any muscles other than those attached to the skeletal system. Experience is necessary to limit our seeking

to paths in which it can be successful. There is no *a priori* reason why it must be successful in these paths and not in others, and consequently our knowledge of this species of causation is just as much dependent upon experience as any other.

These arguments are sufficient to prove that activity experiences have no apocalyptic message to overcome the difficulties and perplexities of causation, but they do not prove in any way that such experiences are not causes at all, and that remark holds of Hume's third argument also. It is true that when we try to raise our arms the endeavour seems an immediate antecedent of the desired effect, whereas, in point of fact, an exceedingly complicated physiological process intervenes. The implication, to Hume's mind, is that these physiological processes are the real cause, and that their precise nature is unknown to us when we try to raise an arm. But, in the first place, Hume does not give a perfectly fair account of the facts. If we try to lift a finger we know that we must contract many muscles of the arm. We include these means in our striving for the end, or, rather, the end is a continuous process which includes these movements of the arm, shoulder and neck. It is false, therefore, that we are ignorant of the intervening bodily chain. We do not, indeed, know it in the way an anatomist or physiologist knows it, but we are aware of it in the only possible way for us, viz. through kinaesthetic sensations and the like; and I have already argued that these kinaesthetic sensations have as good reason to be considered real parts of the body as anything that the anatomist can observe.<sup>1</sup> And in the second place, if the volition is not the *sufficient* cause of the movement of the arm, it may, none the less, be an indispensable part of the process and perhaps the most important determining factor. Hume's argu-

<sup>1</sup> They are characteristic objects of the 'internal sense' as that is interpreted in Chap. III.

ment, therefore, is inconclusive if it be intended to prove that there is *no* reason for supposing activity experiences to be causes. They have at least as good a right as anything else to be considered part-causes.

Unless it is maintained that activity experiences have some peculiar tidings for the metaphysical problem of causality, it is clearly absurd to demand a full explanation of all that causation means in order to justify the statement that activity experiences really are causes. The principle of causation must mean this at least, that events in time are connected according to rules, so that we have reason to suppose that one event makes a specific kind of difference to other events. None of them would exist in the way they do if the others did not exist at their own determinate time, in their own determinate way. Causation also implies a *selective* determination in a special sense of these words. Mill's insistence on the 'sum-total of conditions' has misled logicians into making the attempt to seek their causes in the total state of the universe at any given time. They might just as well, and they frequently do, relinquish the whole notion in despair. What we seek to do, in the attempt to discover causes, is not to expand our enquiry until it embraces all that is, but to narrow it down to those points of presumed connection which are really relevant. If we want to know why Jones has caught typhoid fever we try to discover from what particular spot the germs of the fever have probably come. We are not concerned with the rest of the universe. If we were, there would be little chance of preventing Smith and Robinson from falling victims in the same way as their friend Jones.

In this sense of the words there is no good reason for denying that activity experiences really are causes and may be taken at their face value. Perhaps, however, they cannot claim more than this. The experience of 'force' does not explain causation in general.

•

It is hard to see what it could explain. In any case it does not explain regular or necessary connection. It is irregular and capricious as far as experience goes, and it sometimes succeeds and sometimes does not. And we have already seen reason for supposing that it is very doubtful whether there really is an intelligible nexus between cause and effect even in the case of activity experiences.

Not only are activity experiences causes, but they are peculiarly instructive because of the sense in which they imply selectiveness, initiation and the possibility of genuine novelty. That our seeking is selective is too obvious to require comment. We never seek everything all at once. And enough, perhaps, has been said with respect to initiation. I have tried to show how seeking and choosing seem to initiate, and now we can see that there is no good reason for denying that they really do initiate. It is false, of course, that they alone initiate, and absurd to argue that they are the only causes in the self or in the world. Such a view cannot be seriously maintained. They may have preponderating importance in some selves at all times and in all selves at some times. That is the most that can be claimed for them. And if either initiation or the possibility of novelty meant absence of continuity with other elements, or implied that these other elements were not past causes of the ensuing process, then their claims would have to be rejected. But neither of these implications holds in fact, as has already appeared in the discussion of initiation. Let me give an example of what I mean by the possibility of genuine novelty and the way in which it does not imply complete, or important, discontinuity.

How often do we find, in reading the biography of, let us say, a great poet, that his youthful flights were singularly timid and uninspired? He is the sedulous ape of some other poet, his Pegasus is

•

between the shafts and has cast a shoe. There are no symptoms of genius, but only an attempt to manipulate metres. And then, of a sudden, a new poet is born into the world. The sedulous ape has become a master, never again to return to his old level. In this case there is a real beginning which is not independent of previous events. Without the early trials and failures, without the travail of painstaking apprenticeship, the real poet could not be born. Novelty, in this sense, is a plain fact of which any theory of causation must take account. But it is not independent of previous events, nor could it occur without them.

I have purposely chosen this example because it has no special connection with striving or will. There was as much seeking and choosing at the stage of the sedulous ape as at any other. The new poet is born and does not make himself. And this leads to an important reflection. When Berkeley and others maintain that spirit is essentially active their meaning is plain. They wish to show the distinctive difference between spirit and a moving panorama of sense impressions. The history of philosophy subsequent to Berkeley has emphasised the necessity for recognising that distinction. Spirit is not a resultant of anything else. It lives and moves on its own account. But to say this is very far from saying that spirit is all compact of the particular class of experiences which we call active, or even that other experiences are more dependent on these than *vice versa*. That is an interpretation for which there is no warrant. Cognition and feeling play their part in psychical life as much as endeavour. They are not merely bye-products of endeavour; they are causes in the life of mind as much as endeavour. They have an independent function in that life; they are existent causes. Sometimes an act of will may predominate and seem to sweep the others in its

train. Even then it is not the sole cause, though, perhaps, the most important. But the other elements of consciousness may also predominate in other distinctive phases of the life of the self. To pass from the independence of the self to the primacy of experiences of conation is a *salto mortale*. This point is so clear that it is needless to defend it. If I were to try to do so I should begin by pointing out that cognition is as selective as conation, that it initiates just as clearly, that it lives because of the possibility of novelty, that it exhibits a closer connection between plan and fulfilment than conation itself. But such an argument would not really make the issue plainer.

(3) It remains to give a more precise enumeration of this special class of activity experiences and, in particular, to supply an analysis of will in the narrower, which is also the more accurate, sense of the word. To illustrate the first point I shall quote a passage from the earlier edition of Stout's *Manual of Psychology*. 'Such words as interest, craving, longing, yearning, endeavour, desire, purpose, wish and will, all mark this characteristic of the process of consciousness. All of them imply an inherent tendency of conscious states to pass beyond themselves and become something different, an inherent tendency which continues to operate, unless interrupted by interfering conditions, until a certain end-state is reached, which is called the satisfaction or fulfilment or realisation of the interest, craving, longing, yearning, endeavour, desire, purpose, wish or will.'<sup>1</sup>

It may be true that all the states mentioned by Professor Stout have an inherent tendency to pass beyond themselves, but some of them are attitudes of feeling, not of activity, and the tendency to pass

<sup>1</sup> *Manual*, p 64. In the latest edition the whole passage has been rewritten.

beyond themselves is really their tendency to arouse activity proper. We have already seen that desire is a feeling attitude, a way in which the subject is affected, though it is so closely connected with activity that the two may easily be mistaken. This is still more obvious in the case of interest, and it is also clear in the instances of craving, longing and yearning. We have not, therefore, such an exuberance of examples as Stout mentions here, but we have the facts of consciousness indicated by such words as striving, seeking, endeavour, appetite. There are some slight distinctions between these, but the distinctions (*e.g.* in the case of appetite) refer chiefly to the characteristics of accompanying states of the body. We may pass, then, to will itself.

The exact range of the term voluntary is a matter for dispute. Indeed it is perhaps most convenient to define the term negatively and say with Mr. G. E. Moore<sup>1</sup> that voluntary actions are those which an agent could have done otherwise had the choice been open to him. Even on this definition, however, the fundamental feature of will is choice or its possibility, and the nature of will is seen most clearly in choice after deliberation. The question of resolve need not receive separate treatment, for it is either identical with choice or else means the choice to choose at some date other than the immediate present.

When we deliberate, then, we entertain certain alternatives of action as possible objects of choice. And we must also believe that these objects can be attained through our choice, either directly or indirectly. We cannot, strictly speaking, choose, unless we believe that the object of our choice is within our power. The thought of will implies the thought of 'can'; otherwise there is not will but wish. But when we have summed up the advantages on either side, and compared them in any way in which such

<sup>1</sup> *Ethics* (Home University Library), p. 13.

comparison is possible, we have not yet reached the essence of will. There still remains the element of choice or consent—that *fiat* of the will which is being interpreted, ‘Let it be done, and done through this my choice.’ As the assent of judgment is always more than the entertainment of the meaning of a proposition, so the choice of the will is more than the preliminary deliberation which balances the books. Assent of judgment and choice of will have much in common, but they are also essentially distinct, since the one is a theoretical and the other a practical attitude. If anything can claim to be an experience, choice certainly can. If any reliance can be placed on observation, then, surely, choice influences conduct, determines the current of our psychical life, helps or hinders bodily movement. Both for introspection and from the standpoint of achieved results choice is an active process.

I am glad, in a matter of this sort, to be able to adduce the weighty testimony of Professor James. The passage which I am about to quote deals with the relation between the assent of judgment or belief and the fiat of choice. The analysis of the former seems to me to exaggerate the importance of emotional and volitional characteristics, but that of the latter is, to my judgment, true in almost every line and syllable. ‘To the word “is” and to the words “let it be” there correspond peculiar attitudes of consciousness which it is vain to seek to explain. The indicative and the imperative moods are as much ultimate categories of thinking as they are of grammar. The “quality of reality” which these moods attach to things is not like other qualities. It is a relation to our life. It means *our* adoption of the things, *our* caring for them, *our* standing by them. . . . And the transition from merely considering an object as possible to deciding or willing it to be real; the change from the fluctuating to the stable personal

attitude concerning it; from the 'don't care' state of mind to that in which we mean business is one of the most familiar things in life. We can partly enumerate its conditions, and we can partly trace its consequences, especially the momentous one that when the mental change in question is a movement of our own body, it realises itself outwardly when the mental change in question has occurred. But the change itself, as a subjective phenomenon, is something which we can translate into no simpler terms.'<sup>1</sup>

What is true of the imperative mood is also true of the whole range of endeavour, and analysis can proceed no further. But enough has been said to furnish some indications of the nature of conation, and so to provide a basis for the discussion of its place and function in the self. Let us, therefore, proceed to the consideration of the familiar doctrine that the essence of the self is to be purposive.

<sup>1</sup> *Principles of Psychology*, vol. ii. p. 569.

## CHAPTER VI

### PSYCHICAL AND PURPOSIVE

ALTHOUGH the division between psychical and physical is not exhaustive,<sup>1</sup> it is of great importance, and the usual course is to maintain that the psychical is purposive and the physical non-purposive. When we examine the realm of being we find that there is a broad distinction in the way in which things behave. Behaviour which results from conscious purpose is very different, even to the external observer, from the behaviour of mere matter, and there is much in the behaviour of organic beings which is so similar to purposeful movements, and so unlike merely mechanical action that it is usual to call such behaviour 'purposive' from its analogy to actions inspired by conscious purpose. The extension of the term in this neutral sense is, of course, legitimate and does not call for comment.

The fact that the presence or absence of indications of purpose is the best *criterion* of the existence of mind does not prove in itself that purpose has the primacy among experiences. Indeed, the advantage of the criterion is chiefly that it is an objective test which the external observer can apply, and this is clearly an indirect method of describing conscious processes. None the less the mere emphasis upon the significance of purposive behaviour tends to be

<sup>1</sup> Cf. Chap. II, pp. 16-18.

an argument for the primacy of purpose, and is constantly present in the minds of Voluntarists, whether obscurely or explicitly. The claims of purpose for primacy must therefore be considered from this point of view.

It is unnecessary to challenge the assumption that the marks of purpose are really the best indications of the existence of mind, and their absence the sign of the existence of mere matter. There are some monadistic theories, it is true, which maintain that everything which exists is a self, and consequently that there is nothing in the universe which is non-purposive. But those theories must ascribe properties to matter which, in the ordinary acceptation of terms, it emphatically does not possess. The sun and the planets, we believe, and the whole realm of inorganic nature pursue a magnificent, if sightless, course with unflinching regularity and precision. Their action seems at the opposite pole from that of mind. Psychical beings strive ceaselessly to protect the little corner where they abide, to save themselves from extinction, and to perpetuate the species. They select what will achieve these ends, and reject all else. They adapt themselves to their conditions as well as they can. If their movements are ordered by general laws, the laws must take account of their aims and their interests. To keep their feeble microcosms intact they will make all sorts of shifts which would be meaningless unless nature existed for them as well as through them. Their action thus frequently appears incalculable, and the unity of their lives a unity of individual aims instead of a mere instance of general laws. If you put obstacles in the way of a lover, he may laugh at you for your pains. Deflect a particle, and it will obey without a murmur. What wonder, then, that this very marked difference should be seized upon as the real *differentia* of selfhood?

‘*De facto* purpose,’ as Professor Bosanquet assures

us, 'is a psychological, temporal and ethical idea,'<sup>1</sup> and he seems to imply that its claims may, therefore, be slighted. But purpose, even at the humble level of psychology, time, and morals, is sufficiently ambiguous to invite discussion, and so are 'end' and 'teleology.' They also are ambiguous, as Professor Bosanquet ably argues, when they are taken at his 'higher' level, and he is probably right in asserting that the principle of Teleology, when applied to the Absolute, vanishes in favour of something else. For this reason, as for so many others, it is imperative to begin this enquiry by examining the various possible meanings of teleology, end, and purpose, and the relations between them.

The most usual and the most natural sense of the word purpose is that which is implied in conscious striving or conscious choice. What we seek to do, or what we strive to do, is our purpose. In this case we are consciously aware of the end, and endeavour to bring it to fruition. But 'purpose' and 'purposive' are also used in a wider sense, not always identical with the natural extension of the term 'purposive' which has already been mentioned. In the first place the terms are frequently applied to any process which appears to be directed to an end whether that end be in fact present to consciousness or not. Thus instincts are said to be purposive because they appear, to an external observer, to be like processes which consciously strive after an end. But the animal which acts instinctively need not be conscious of the end at all. On a still more extended usage, life, of any kind, is sometimes called purposive. Or, again, the claim is frequently made on behalf of certain idealistic theories that they are teleological. In this case the reason is that idealists attach so much importance to values and ideals in their interpretation of existence. That is one of the implications

<sup>1</sup> *The Principle of Individuality and Value*, p. 127.

of the simile that the universe depends, in the end, on the idea of the good, as sensible things depend on the sun. Indeed, those who are idealists usually base their belief on this ground. They welcome idealism rather because it is a city of refuge for ideals than because it exalts 'ideas' at the expense of matter. And there is yet another respect in which idealism may be called teleological or purposive. Purpose refers to final causes, and perhaps there is no final cause except the whole. Idealism insists that the cosmos is a perfect whole. In this sense teleology means the explanation from whole to part. How is it that one and the same term can have such diverse interpretations and may be used to justify so many theories?

The fact is not very difficult to explain even with regard to those cases of 'finite and outward design' which Hegel ranked so low. Even in their case it is clear that end may expand into something like system, and is closely connected with value. There are analogies to both in explicitly conscious purpose, and extension by analogy seems the essence of the argument here.

It is usual to draw a distinction between end and means. Mr. A wishes to cross the Atlantic in order to see his friends, and so he books his passage on some liner. To distinguish end from means is easy enough in such an instance, and it is not difficult to specify the characteristics of either. The end is distinct from the means, and the means are directed towards it; the means are selected with a view to the end, and are adapted to the conditions which render the attainment of the end feasible; and both means and end are restricted, specific, particular. But even this analysis soon leads us to perplexities and intricacies.

What precisely is the relation of means to end from the point of view of psychical analysis? When the means are external to the end, as in the choice

of a steamship or a railway train, the relation seems only that the means are instruments for attaining the end. But even in this instance Mr. A plans, not merely to see his friends, but a whole expedition, and the voyage or the journey is an integral part of this whole. And how, when we consider a long process of striving towards a goal with the hindrances incidental thereto, are we dealing solely with an instrumental relation, and in what sense is the end really distinct from the means? Or let us take another instance. A student wishes to take his degree and prepares himself for examination. If his end is only the right to append certain letters to his name, and wear a hood, and receive an academic benediction, then, no doubt, there is a clear and well-defined distinction between end and means. But if he has sufficient intelligence to desire the degree as a token of efficiency and knowledge, then there is at least no temporal distinction between end and means, between the proficiency and the preparation, for he becomes proficient in so far as he prepares. And, again, the degree is not the be-all of his existence. It may be merely a means towards obtaining a competency or it may be that and also an end in itself.

This example is sufficient to show that means and end are often closely interwoven, and many writers are driven by these difficulties to deny that the ends which we choose are really ends at all. The proximate end of any particular choice or striving is often far from being an end in itself. Psychologists usually describe these proximate ends by saying that they are the end states of particular conative processes, and that, when they are attained, one conative process ceases and another succeeds. But this account is mistaken. Suppose our proximate end is to eat a good dinner. The end state of that dinner is the last mouthful of dessert or the last sip of coffee. When this is attained the conative process

ceases, but the end-state is not the end or aim of the process. It is not the object of our striving, but only the last state in time. We might as well maintain that the aim of a hungry man is satiation. He aims, not at satiation, but at a good square meal.

Accordingly it is maintained that the end of a conative process should in no respect be regarded as the last state in time of that process but as the completion or completeness of that process, and in that case *every* part of the process will form part of its completion, since all are necessary to it as a whole. Similarly it may be held that the end of a process is not satiation, but satisfaction, and this again has no specific reference to the last state, in time, of the process. These views are clearly much more adequate than the former (even to express the nature of finite particular conations), and I have but one criticism to offer. The satisfaction is not the direct object of a conative process. It is a feeling attitude which accompanies attainment and prompts to fresh attainment, but it presupposes that attainment and it is *found*, not sought directly. The principal arguments against psychological hedonism are fatal also to the doctrine that satisfaction is the object of choice. We choose objects, not satisfaction, except in and through their attainment. To get satisfaction we must forget it.

It is clear, therefore, that the consideration even of particular plans brings us near to the question of totality, and this implication is still clearer when we remember that even the ordinary man does to some extent subordinate his particular aims to the plan of his whole life. Accordingly any explanation which proceeds from whole to part is sometimes called teleological; and wholeness and completeness is often said to be the principal characteristic of purpose. In this sense anything which acts as a whole in any marked or peculiar way is sometimes said to be therefore purposive. •

And the implication, or the possible implication, of value is also manifest. When we choose to do anything we ought to choose the action because it will bring about more value, on the whole, than any other which is open to us. No doubt we frequently act otherwise than as we ought. We sometimes knowingly choose to do things which we have no reason to suppose will conduce even to our own private and particular welfare. But we always consider them worth doing from some aspect and from some point of view, and this is what appeals to us at the moment of choice. Any process, therefore, which is directed towards the attainment of value is sometimes called purposive.

Is the self, then, distinctively a purposive entity in some one of these senses or in all of them? Probably every one of these implications occurs at some one time or other in arguments upon the subject. In modern days, however, most of the discussion centres round biology. The behaviour of living beings, it is argued, requires the conception of purpose or something analogous to it, in order to become intelligible. There are two great classes of existent beings, those which act mechanically and those which act purposively, and purposive behaviour either implies a self in every instance, or selves form a sub-class of purposive beings. 'We may then define psychology as the positive science of the behaviour of living things. . . . We all recognise broadly that the things which make up our world of perceptible objects fall into two great classes, namely, inert things, whose movements and changes seem to be strictly determined according to mechanical laws, and living things, which behave or exhibit behaviour; and when we say that they exhibit behaviour, we mean that they seem to have an intrinsic power of self-determination, and to pursue actively or with effort their own welfare and their own ends or purposes.'<sup>1</sup> Let us

<sup>1</sup> M'Dougall, *Psychology* (Home University Library), pp. 19, 20.

consider this question more precisely in order to discover, if possible, why life of any sort should be called purposive. The problem of the meaning and adequacy of mechanical categories in biological explanation is, of course, a technical one which can only be decided by experts on the subject, if, indeed, it can be decided by any one. The layman must walk warily and has no right to expect that his personal views are entitled to any particular respect. But he is entitled to discuss the general nature of the arguments adduced and to consider what they could prove if they were shown to apply.

The range of the term 'purpose,' as used in this sense, is clearly a very wide one. It must apply to physiology as well as to psychology, to plants as well as to animals, to digestion as well as to ratiocination. This, for instance, is the wide meaning in which Schneider uses the term. 'When oxygen combines with iron and thus produces rust this is not a purposive process. But we have behaviour according to purpose when oxygen is combined with the carbon in our blood and so promotes our conservation.'<sup>1</sup> The term purpose has here no special implication of conscious striving. It means only conduciveness to an end which has value. In this sense, any feeling, organic or psychical, any impulse or instinct that helps the animal in the struggle for self-preservation or the preservation of the species should be called purposive. The problem is whether explanation in terms of purpose is really significant, when analogies are pushed so far, and in so many directions.

The arguments in favour of neo-vitalism—for it is these which we are discussing—have a negative and a positive side. They state (negatively) that the behaviour of living beings cannot be explained in terms of mechanism, and (positively) that the explanation which mechanism cannot afford must be

<sup>1</sup> *Der thierische Wille*, p. 24.

sought in something analogous to immanent purpose. External teleology, the kind of purpose invoked by the Argument from Design, is, of course, irrelevant to the question since it is perfectly compatible with mechanism. God made a machine which works according to the Laws of Motion.

Let us, then, consider the negative arguments. The behaviour, even of the lowliest organisms, exhibits characteristics to which there is no real analogy in the inorganic world, and consequently it is a mistake in principle to attempt to explain them by categories which have proved their worth in that world only. No machine, and no collection of particles, exhibits the phenomena of restitution, reproduction, adaptation, selection, or persistence in a certain direction despite all obstacles. A ship cannot regenerate a lost propeller. A newt can regenerate a lost leg. 'Thus we see that, at the very bottom of the evolutionary scale, animal behaviour exhibits the two peculiarities which at all higher levels also distinguish it from the movements of inorganic things, namely, (1) the "total" or unitary nature of reaction, *i.e.* the reaction of the organism as a whole with co-ordination of the movements of its parts in response to a stimulus directly affecting one small part only; and (2) the persistence of the effect of the stimulus, a persistence closely analogous to that persistence of varied movement which in ourselves and our fellows we recognise as the expression of a persistent effort after a desired end. And to this it must be added that these persistent and varied and total or unitary reactions of the whole organism are in the main adaptive, *i.e.* of such a nature as to promote the welfare of the creature.'<sup>1</sup>

<sup>1</sup> McDougall, *Body and Mind*, pp. 260, 261. This is really a *negative* argument, and it occurs in the chapter entitled 'Inadequacy of Mechanical Conceptions to explain Human and Animal Behaviour.'

Now before considering the positive side of the contention of the neo-vitalists (and they are disagreed upon it), we ought to remember that a negative argument is of two kinds, and that these kinds carry very different degrees of weight. It may be a disproof of possibility, or it may be merely a proof of failure. If the neo-vitalists could prove conclusively that mechanical categories could not possibly explain animal behaviour, then biologists would be compelled to seek some other type of explanation. If, on the contrary, they could only prove that biology is still, in many respects, an occult science, and that the principles of nineteenth-century biology have not succeeded so well as was expected, then the biologist of the twentieth century might reasonably seek some other hypothesis, but would not be compelled to do so. The *lacunae* and the failures of science are apt to prove themselves far from unsurmountable.

Professor Driesch is one of the best-known exponents of neo-vitalism, and he is fully aware of this difference in the probative value of negative arguments. Indeed, he discriminates between his own arguments from this point of view, as a brief reference to the first of his recent lectures on *The Problem of Individuality*<sup>1</sup> will show. The point in dispute is whether a machine can or cannot be the source of life, and Driesch admits the theoretical possibility that the machine theory could explain some of the instances which are *prima facie* favourable to the opposite view. It is not intrinsically absurd, he maintains, that adaptation and immunity could be mechanically explained, although there is no known machine which can, *e.g.*, produce an anti-

<sup>1</sup> These lectures give a condensed and very clear summary of the argument of the earlier *Gifford Lectures*, entitled *The Science and Philosophy of the Organism*. The shorter form is better fitted for the purpose of a rapid survey like the present. It is also the more recent presentation of the argument, and the logic of it is just as clear.

toxin to rust. The same is true of regeneration. We know of no machine which is capable of restoring itself, and so the probabilities are in favour of neo-vitalism. But there is no direct contradiction in the conception of such a machine.

Driesch contends that the facts are otherwise with regard to morphogenesis. He was able to show, by experiment, that in certain cases artificial interference with the embryo will not affect the normal course of the development of the organism, except in the way of reducing its size. These experimental results were varied and striking, but the mention of his early discoveries with regard to the development of the sea-urchin will suffice to indicate the logical bearing of his argument. 'The so-called "cleavage" of the egg . . . ends in the formation of the *blastula*, i.e. a hollow sphere built up of about a thousand cells, forming an epithelium. If you cut this *blastula* with a pair of very fine scissors in any direction you like, each part so obtained will go on developing—provided it is not smaller than one quarter of the whole—and will form a *complete* larva of small size.'<sup>1</sup> Facts of this kind, Driesch maintains, stand in plain logical contradiction to the very meaning of a machine. A machine is 'a given specific combination of specific chemical and physical agents,'<sup>2</sup> and an arbitrary and random disarrangement of a machine could not leave its equilibrium unaffected.

This argument seems inconclusive. In the case of the *blastula* of the sea-urchin the smallest fragment which is capable of developing as a whole is one quarter of the original *blastula*, and therefore must contain at least 250 cells by Driesch's own computation. Similarly, in the other cases, the fragments must be relatively large and complex. If, then, there is no logical contradiction in the mechanistic account of the normal development from

<sup>1</sup> *The Problem of Individuality*, p. 11

<sup>2</sup> *Ibid.* p. 17.

a complete *blastula*, it is surely not absurd to explain Driesch's results by saying that fragments of the *blastula* may develop into complete, though smaller, organisms in those cases in which the arbitrary dissection of them results in leaving a sample which contains all the requisite physical and chemical ingredients. The laws of averages would make such sampling not intrinsically improbable.

It is scarcely surprising, therefore, that many of the neo-vitalists themselves dissent from Driesch with regard to this argument.<sup>1</sup> It is impossible to refute mechanism absolutely, although some statements of the mechanical theory may be intrinsically absurd. On the other hand, the negative arguments certainly prove that there are great difficulties in the mechanical conception, and the principle of the economy of hypotheses may be in favour of neo-vitalism.

The positive formulation of the vitalistic or neo-vitalistic argument differs greatly in different authors and sometimes does not appear at all. Indeed, the negative side of the argument is much stronger than the positive. Still, the positive formulations when they occur are in strict conformity with the rules of inductive procedure. A hypothesis must be framed upon analogy; and it is maintained that the true analogy in this case is derived from psychical purpose. Driesch, for instance, calls the teleological factor in action, which he postulates, a 'psychoid.' 'I propose the very neutral name of psychoid for the elemental agent discovered in action. "Psychoid"—that is, a something which, though not a "psyche," can only be described in terms analogous to those of psychology.'<sup>2</sup>

<sup>1</sup> Cf. J. S. Haldane, *Mechanism, Life, and Personality*, p. 27. 'There is no evidence at all that each cell, in growing and dividing in the one particular manner which constitutes normal development, is not determined by special physical and chemical stimuli peculiar to its position relatively to the other cells, and to the external environment. We do not yet know what these stimuli are; but probably no physiologist would doubt that they exist, and will be discovered when our methods are fine enough. Hence Driesch's argument for an independent vital force breaks down entirely.

<sup>2</sup> *The Science and Philosophy of the Organism*, vol. ii. p. 82.

He distinguishes this 'psychoid' of action, however, from the teleological factor in morphogenesis or restitution. For it he reserves the still more neutral name of entelechy. Dr. M'Dougall, however, does not draw these subtle distinctions. 'The embryo *seems to be resolved* to acquire a certain form and structure, and to be capable of overcoming very great obstacles placed in its path. . . . This power of persistently turning towards a particular end or goal, manifested in these two ways, namely, in growth and bodily movement, is the most characteristic feature of the life of organisms, objectively regarded. It seems to involve essentially teleological determination, that is to say, it seems to be essentially of the same nature as the striving towards a goal or end that runs through all our inner experience, the goal being present to consciousness with extremely different degrees of clearness and fulness. . . . The processes seem to be essentially teleological, that is to say, they seem analogous to the behaviour of organisms, which from analogy with our own experience of purposive striving we believe to be prompted by psychical impulse and, in the more highly developed organisms at least, governed and guided by some prevision of the end to be achieved.'<sup>1</sup>

Hypothesis rests on analogy; but some analogies are good, and others not so good. Our question is, On what grounds of analogy are we led, or compelled, to believe that purpose is *the* essential characteristic of all life? The best way to approach this question is, I think, to consider those cases in which purpose unquestionably occurs, and then to attempt to discover how far there really is an analogy in cases which seem more doubtful. And this, as we have seen, was the way in which biology quite legitimately came to use the word purposive. Granting that some behaviour is not a mere reflex but implies conscious

<sup>1</sup> *Body and Mind*, pp. 242, 243. (Italics mine)

direction and purpose, then any behaviour which resembles this in important respects may well be called 'purposive' whether there is proof of conscious purpose or not.

We have every reason to believe that the choice of will influences action. Choice and resolve, especially after deliberation, demand the presence of rational reflection: they are antecedents of the ensuing actions: and there is no good reason for denying that they are determining antecedents. Here, then, is a case of action which is really purposeful and not merely purposive, which is due to the *psyche* and not merely to the *psychoid*. Similarly, as was argued in last chapter, purpose in the sense of conscious striving after a conscious end does work effects. And it is also true that these processes may persist for long in face of obstacles, and may try all means of attaining their end. They may also be consciously subordinate to a general plan of life. But they need not be.

When, however, we come to the case for the psychoid we come to what is really a very weak analogy. Let us take, for instance, the whole range of instinctive action. The great instincts, no doubt, involve conscious striving, a 'unitary' process and the rest; and their striving is directed towards an end. But so far as introspection goes they are consciously directed towards a proximate end only, and not towards the welfare of the organism as a whole or of the species as a whole. Even in human experience the instinct of sex at the time when it is strongest is not consciously directed towards its biological end—the perpetuation of the species. The youth seeks the maiden because he loves her and wants her, and not for the sake of his duty towards posterity. He does not choose his mate for the reasons that actuate the breeder of pedigree stock. If he did, there would be no need for the apostle of eugenics. And if this is true of the human species,

is it not even more profoundly true of other animals? The very perfection of many animal instincts seems to show that they cannot, properly speaking, be conscious of their end. The male and female larvae of the stag-beetle are of the same size, but the male larva builds itself twice as big a hole. There must be room for its horns to grow, but is it possible to believe that the larva has any consciousness of this fact? 'Instinct,' says Hartmann, from whom the above example is chosen, 'is conscious willing of the means to an unconsciously willed end.'<sup>1</sup> But the means are not consciously willed *as means*. Certain ends are chosen which do, in fact, lead to a further end which is biologically useful. But this does not imply the vaguest degree of knowledge of what the biological end is. To say that it is known dimly or implicitly is as important a piece of information as to say that we all know, dimly and implicitly, what life is or what are the implications of Euclid's axioms.

And if this holds of instinct surely it holds, *a fortiori*, of growth. Each of us, with individual variations, grows to the form and stature of a man, and each wishes to do so. But we do not, strictly speaking, choose or try to do so. Profiting by the experience of others we may aid and abet the process in various minor ways. We may play games and eschew cigarettes. But we do not grow to be men by taking thought. The strong and healthy man does not try to be strong and healthy in any sense in which his weaker brother does not make the same attempt. He *becomes* strong and healthy. It is not surprising that conscious purpose should exhibit some analogies to bodily behaviour, since the body is the instrument of action, and its behaviour is our only or our most important clue to the existence of any conscious purpose other than our own. But to

<sup>1</sup> *The Philosophy of the Unconscious*, vol. i. p. 88.

suppose that digestion, for instance, or other bodily processes of a similar kind, participate in consciousness even in the vaguest degree is to mistake fable for fact. We might as well believe that Menenius Agrippa related an actual historical conversation between the belly and the other members. And when we leave the higher animals and come to lowlier animals and to plants, what reason have we for attributing anything like conscious purpose to them?

The 'psychoïd,' doubtless, has too much in its favour to be summarily dismissed. What I am urging at present is that there is a difference in kind between that which *de facto* makes for the conservation of an individual or a species, and therefore may be represented as a means to this end, and that which is consciously chosen in order to bring about this result. Nobody maintains, of course, that a beaver builds a dam or an infant seeks the breast with a conscious foreknowledge of the biological utility of such actions, and an explicit resolve to promote that utility. If it were so, the infant would have a surer and more reasoned knowledge of the nature of things than the majority of adult men, and a casual assembly of politic rooks in a field have the collective wisdom of the British House of Commons.

It is true that the range of conscious purpose extends further than is frequently supposed, and also that there is a wide domain of subconscious purpose. The evidence which, *e.g.*, has been collected by Freud<sup>1</sup> and others concerning the rôle of repression in forgetting seems to leave no doubt on this head. But the realm of the subconscious, by its very definition, exhausts the cases in which there is any justification for supposing that anything analogous to consciousness (in an important sense of analogy) enters; and, therefore, it is necessary to remember that there is

<sup>1</sup> Vide his *Zur Psychopathologie des Alltagslebens und Traumdeutung*.

much in the sphere of the organic in which there is no reason to suppose that any subconscious purpose plays its part. When that is the case and there is a difference in kind, it is futile to speak of purposive determination, and, consequently, there is no justification for believing in the primacy of will. Instinctive action is an instance in point. Conscious purpose enters frequently into such action, and may even be present, through inheritance, on the first occasion in which the instinct is called into being; for some believe that meanings are inherited. There is, therefore, no need to return to the ancient doctrine that Instinct must differ *toto coelo* from Reason, or to say, with Pope, that when Reason is at fault

. . . honest Instinct comes a volunteer,  
Sure never to o'er-shoot, but just to hit;  
While still too wide, or short, is human Wit.

But, on the other hand, conscious and subconscious purpose, by themselves, are quite incapable of explaining *every* instinctive action.

To illustrate this point I may refer to Professor Stout's very interesting discussion of the inheritance of meanings.<sup>1</sup> It is generally agreed, nowadays, that instincts are modifiable through experience of the success or failure attending their action. But it is still maintained that such complicated actions as nest-building, migrating, and the like are performed blindly on the first occasion without any prevision of the end. That is much more than a denial that there is any awareness of the biological advantage of performing the action prompted by instinct. The chances are that no animal, other than man, is ever aware of this. The argument is that the animal, at the first time *e.g.* of nest-building, has no awareness whatever of what it is about. It acts from merely biological causes. To this Professor Stout answers,

<sup>1</sup> *Manual of Psychology*, 3rd edition, Book III. Part I. chap. 1.

I think conclusively, that the process has all the marks of intelligence on its first performance. The animal is alert, attentive, and not merely aware of something happening inside it, as it ought to be on the purely biological view. Moreover, the fact that there is adaptation of instinct through experience seems to show that the development is continuous. It is a modification of experience through further experience, and consequently there is not a difference in kind between the first performance and the subsequent ones. It would seem, then, that instinctive action, even at its first performance, implies a degree of intelligence which cannot be completely accounted for by the previous experience of a particular animal. But one of the merits of Professor Stout's discussion is the careful way in which he limits the presumption, if not the proof, that meanings are inherited. The factors, analogous to conscious purpose, which it is necessary to assume as part of the being of instinctive action, are very restricted. 'It is only necessary to assume an awareness of the present state as transitional—as something which not merely *is* but *is to be*. Such rudimentary reference to the future is not wholly indeterminate; it is specific inasmuch as it is concerned with the further development of a specific situation and, more particularly, of certain selected factors within it. It is vague inasmuch as the animal has no clue to the particular nature of the changes which are to take place. The important point is that the situation is apprehended as alterable. This is enough to make conation possible.'<sup>1</sup> If then the part which purpose, even in the dimmest sense, plays in instinct is very restricted, how much more is it restricted in ordinary processes of growth, alimentation and the like. Why do we need the 'psychoid' for all biological explanation?

Indeed, if the behaviour of organisms is to be

<sup>1</sup> *Manual of Psychology*, 3rd edition, Book III. p. 355.

explained by the concept of purpose, it is by purpose in the sense of explanation from whole to parts—which is another matter, though not totally devoid of analogy to the purposes we know. In that case three questions are implied. (1) In what sense is explanation from whole to parts legitimate? (2) In what sense is it required for the explanation of the organic and not required for the explanation of the inorganic, and may not the former sense make it unnecessary to believe in the existence of a distinct and peculiar ‘vital’ or ‘purposive’ factor? (3) Is it not possible that the principles of biology need not be identical *either* with those of psychology *or* with those of mechanism?

(1) To explain anything is simply to give a systematic account of it, and if a reference to the whole introduces system in our comprehension of it, then explanation from whole to parts is, *eo ipso*, legitimate. In this sense it is legitimate to say that inflammation means an increase of the blood pressure in a certain area of the organism in order that a foreign body detrimental to the organism may be expelled or destroyed. Or, again, it is legitimate to explain the fact that the brain of a man who dies from starvation is still well-nourished as compared with the rest of the organism, by saying that the brain is pre-eminently important from the point of view of the organism as a whole. But it is a different thing to examine the matter more closely and explain what this teleological factor is.

The main point to notice is that it cannot be a factor or element co-ordinate with the parts. It is irrelevant whether it exercises energy or, as is the case on Driesch’s theory of the entelechy, it only exercises guidance without work. The latter conception may be useful, even essential, in explaining the rôle of consciousness in the production of movement. If the law of the conservation of energy must

apply to the organic as well as to the inorganic—and that cannot be proved, though certain experiments may show it to be probable—then we must employ this conception. But it is always meaningless to assert that the whole, as an element distinct from or additional to its parts, can either work or guide without work. The *idea* of the whole may guide conscious action, because it is possible to think only of the general characteristics of the whole, and this idea is particular like other ideas, or, rather, the act of reference to such a general idea is as particular as any other act. But to speak of the whole as an entity co-ordinate with other parts is to make the whole a particular—as Hegel emphatically maintained.

Wherever there is systematic connection of any sort, there the conception of whole is as necessary as that of parts. Whole and part are in fact correlative notions for explaining a given set of facts, and neither of them are factors or elements *in* those facts. The real question is how far elements in a whole can be said to remain the same elements when they enter into some other combination. Have we any right to believe that the same substances can be parts of different wholes at the same or different times? As we shall see when we come to discuss the nature of substance, there are several senses in which they can.

The question itself is one of degree. Transfer a brick from one heap to another and it seems obvious that the brick remains the same and that the two heaps are also, to all intents and purposes, identical. Take a brick from its place in a building, however, and the building, at least, will seem to have changed. Take a cell or collection of cells from an organism, and the cells will certainly change. They will become mere matter, while the organism, until it can either restore the cells or otherwise compensate for their loss, will also be affected by the change and cease to be precisely the same whole. In every one of these

instances a part is taken from a whole. The only question is the intimacy of the relation of parts to whole.

It is futile to argue that the question hinges upon quality and relation, or to say that when anything becomes part of a new whole all that happens is that it changes its relations. That may, or may not, be the case, but it is just as essential to include relations in treating of part and whole as it is to include quality. The whole is the parts as they are related together, and nothing more. It is not the parts considered as an aggregate to the neglect of all save numerical relations, nor is it the parts considered in other relations. It is not even true that we can ever consider the parts separately from the whole. That which we call a part when we consider it as a member in a whole may be considered 'separately,' provided it remains relatively the same when considered in itself or as a part of some other whole.

(2) Accordingly the real difference between organic and inorganic categories is only that, in the sphere of the inorganic, that which can be considered (at the same or at different times) part of different wholes remains relatively the same, while, in the sphere of the organic, there is not the same relative identity but a very marked difference. And as parts and whole are correlative, the arguments which hold of the parts will also hold, *mutatis mutandis*, of the corresponding wholes. To postulate an additional factor, as vitalism does, is at least not logically necessary. It may be true that each organism acts as it does because it is impelled by some sort of conscious self. But, unless this factor can be proved to exist, it is not called for in order to explain the different behaviour of organic and inorganic in the phenomena of restitution, elementary morphogenesis, and the rest.

But, it may be argued, there is a relevant difference. Organisms can assimilate. Grass assimilates

the inorganic soil, sheep assimilate grass, and men assimilate sheep. How is it possible that the same material when assimilated behaves so differently from the way it behaves when not assimilated? If organic bodies were formed of a different kind of substance from inorganic things then the foregoing argument might be justified, but if they are not, and if, as we have reason to believe, every body is recruited from its environment in such wise that, after a certain interval of time, no part of the original substance of the organism remains, how is it possible that the parts of an organism should behave so very differently from the parts of inorganic things? There is no mystery here if a single vital principle continues to actuate the organism. Unless it does so there is not merely mystery but miracle.

But is there really any greater mystery here than in many other facts which science accepts without question? Is there really anything mysterious (in the sense of unusual or irrational) in the fact that entities forming part of a certain whole exhibit different characteristics from those which they show as members of some other whole? If a silk handkerchief and a piece of amber are rubbed together, the result will be that electrical phenomena appear. But neither the amber nor the handkerchief is itself electrical, and yet there is electricity when they are connected in a certain way. It is not unusual to talk of the latent electricity which appears on occasion of the rubbing of these two, but to talk in this way is not to think. And even if the theory were true it would not prove that a single vital principle animates each particular organism, but only that when certain particles of matter become connected in the form and fashion of an organic body there latent life will become actual. This difficulty, accordingly, is not really serious.

In short, although the behaviour of organisms is

very different from that of inorganic matter, and may very well require distinctive principles of explanation, it does not follow, in any way, that these new principles are absolutely heterogeneous from the old. They need not differ more from the old than, let us say, tropism differs from gravitation or electricity from the laws of motion. And if they do differ, if it is false to call the body, as Descartes did, 'cette machine composée d'os et de chair,' if they even, in some sense of that much-abused word, deserve to be called 'teleological,' it does not follow that this 'teleology' can only be explained by postulating the influence of a permanent psychical being. If such a being were really present neo-vitalism would not differ from vitalism except in so far as it expresses itself in a more exact and guarded manner. A distinct new entity would be presupposed, viz. consciousness.\* But there is no sufficient ground for supposing that such an entity is always present where life is. The reasons for believing so rest on very vague analogy, and on analogy which fails precisely at the points where it ought to be most helpful. The 'psychoïd' is a mongrel which skilfully conceals any *conscious* strain. There is no evidence that it is conscious in any degree.

(3) If these arguments are sound, it will follow that it is a mistake in principle to maintain that the existent universe contains two classes of beings, the 'mechanical and the purposive, if the word purpose implies anything that can truly be said to be consciousness. If we must subdivide in this way we should speak of the inorganic, the organic,<sup>1</sup> and the conscious. The conscious, however, when it is found, is always found in alliance with an organism, and it

<sup>1</sup> 'The organic,' in this sense, means the whole realm of living things. A distinction, however, may be drawn between their *organisation* and their *organic constitution*. A more accurate usage would therefore be to define 'organic' as meaning carbon compounds, and to mention the characteristic of being *organised* when describing living beings. ♣

is therefore not unreasonable to suppose that consciousness is only a sub-class of life though not co-extensive with all life. We shall conclude this chapter by discussing the question. But we need not discuss it at great length, because we have already been discussing it frequently. We were discussing it when we distinguished the self from the body, when we distinguished psychical endeavour from bodily sensations which accompany it, when we showed that the central rôle of the body in action was only remotely analogous to that of feeling in the self. The nature of consciousness is to be a reference to an object. That is no part of the nature of the body. It is not, as such, conscious, and so far as it enters into relation with consciousness its being is to be an object for consciousness and an instrument of consciousness. The existence of the body may be a necessary condition for the existence of consciousness, but the nature of consciousness is fundamentally distinct from that of the body.

Another distinction which might be mentioned is the all-important one that cognitive processes may be valid and volitions may be right (from the point of view of ethics), while there is no sense in attributing validity or moral rightness to processes of the body. Any one except a pragmatist or a materialist must assent to this statement, and the pragmatist would only dissent because he mistakes the way in which a process may lead up to and terminate in another process for the true awareness of the meaning of that process. I do not say that this is a universal characteristic of all consciousness. Conscious logic is often faulty, conscious action often wicked. The laws of logic are not the ways in which men always think, or the laws of ethics the ways in which they always act. It is not necessary to agree with Descartes when he says, 'As to the Reason or Sense, inasmuch as it is that alone which constitutes us

men, and distinguishes us from the brutes, I am disposed to believe that it is to be found complete in every individual.<sup>1</sup> But the fact that truth or falsity, rightness or wrongness, are characteristic of some conscious processes though not of all, while they are never applicable to bodily processes, shows at least that some conscious processes are not bodily processes, and supplements the independent arguments which prove that the two are distinct.

When we come, in a later chapter, to consider the unity and continuity of psychical processes we shall find still further confirmation of the distinctions we have drawn here. Meanwhile, at the risk of repetition, I should like to point out the bearing of the argument of the present chapter on the general question of the primacy of will in the economy of the self. If it is maintained that the *differentia* of selfhood, at any level, is that it is purposive, and that the absence of purpose distinguishes mere matter from the rest of the universe, then it is not unnatural to conclude that this distinguishing feature is the real essence of any being which is not mere matter. And if it is held further that purpose is the spring of life, then, because the self is alive, it is easy to draw the inference that all experiences are simply various manifestations of purpose. The arguments of this chapter, if they are sound in any respect, will suffice to prove that this interpretation is needless; and so we may pass to the consideration of some other arguments in favour of the primacy of will.

<sup>1</sup> *Discourse on Method*, Part I

## CHAPTER VII

### THE PRIMACY OF THE PRACTICAL REASON

THE two previous chapters have shown that the proofs of the primacy of will are drawn from a variety of sources, and that the ambiguity of the word 'will' is partly responsible for this result. It may seem gratuitous, therefore, to introduce a phrase which is possibly still more ambiguous, *i.e.* the practical reason. When Schopenhauer maintains that the will is the thing in itself and everything else an appearance derived from it, he means by the will an insatiable impulse to life, something, in fact, very like Bergson's *élan vital*. This sense of will, whatever it is, is clearly different from volition in the narrower sense which is peculiarly relevant to ethical choice. On the other hand, when Kant tries to prove the primacy of the practical reason over the speculative he is referring to this narrower sense strictly. Closer inspection will show, however, that the difference is not so great as might be supposed, at least with regard to the way in which these authors define their terms. The will, for Kant, is synonymous with the practical reason. 'Everything in nature works according to laws. Rational beings alone have the faculty of acting according to the conception of laws, that is, according to principles, *i.e.* have a will. Since the deduction of actions from principles requires reason, the will is nothing but practical

'reason.'<sup>1</sup> And Kant also says, 'The appetitive faculty is the faculty of being by means of one's ideas the cause of the objects of these ideas. The faculty which a being has of acting according to its ideas is life.'<sup>2</sup> It is strange that any one should have adopted a definition of life which implies that honeysuckle, being alive, is, through its ideas, the cause of the object of these ideas. But thus it was. And although causation through ideas is not identical with action according to the conception of law, still the gulf between them is not impassable.

For the rest, I have chosen the title of this chapter in order to emphasise the precise nature of the subject considered in it. I wish to deal with the *metaphysical* arguments for the primacy of will, and I shall keep in mind principally the treatment of the question during the great constructive period of German philosophy. From this point of view it is most convenient to follow our authors in chronological order. The reader will remember the well-known saying that the history of philosophy is thought itself taking its time.

The primacy of the practical reason is the keystone of the arch of the Kantian system, at least so far as that appears in the first two *Critiques*. Kant's thesis is that the practical reason has the first place in comparison with the speculative, and this assertion of the secondary importance of the intellect as compared with the will forms the thread of continuity between all the arguments that call for mention in this chapter. Kant did not, indeed, contend that there are two distinct entities, the theoretical and the practical reason. On the contrary, he held that one and the same reason has both a practical and a theoretical use. But the practical use of reason has

<sup>1</sup> *Fundamental Principles of the Metaphysic of Morals*, Abbott's translation, p. 29.

<sup>2</sup> *Introduction to the Metaphysic of Morals*, Abbott, p. 265.

the prerogative of being the first determining principle.

In ethical choice we are confronted with a *fact* of pure reason, the fact that it is practical. To act rightly is to act in accordance with the conception of universality, and such action must be *universal* in a double sense, since it must apply to every rational being, and also in every possible circumstance. Any exception, in either sense, destroys the universality. Nor is it enough that the action should, in point of fact, be universal in these ways. A man may keep all the ten commandments from a wrong motive. The important point is that the agent should choose the act *because of* the universality. He must do it because he wills it to be universally practised; and so it is permissible to argue that action is morally right if and so far as the concept of universality is the determining principle. When that occurs we have the 'fact of pure reason,' and the existence of such a fact must be admitted. True, it may be impossible to prove that any given action is wholly and completely right. Some empirical and, therefore, non-rational motives might have helped to determine it. Some alloy of self-interest might have entered, as in the cases when a man knows that doing his duty will also conduce to his own advantage. Such an act, according to Kant, would not be a perfect instance of ethical action. Universality would not have been the sole determining principle. But it would clearly be absurd to argue that because we can never prove that a given action is completely disinterested, we should therefore conclude that action is never disinterested in any degree. We may, then, admit this *fact* of pure reason.

Since the basis of Kant's argument is the fact of moral choice, it seems a clear duty to consider whether he really gives an accurate account of that fact. Fortunately, however, the most serious objections

refer only to the *sufficiency* of his account, and its insufficiency need not affect the validity of his further argument. It is true that his conception of universality may require reinterpretation. There are no good grounds for maintaining that any action must be right for all agents in all circumstances. It is generally a duty not to commit suicide, but a community has a right to anticipate its fate at the hands of a savage foe if further resistance is hopeless, and capture would involve something worse than death. It may be A's duty to take a holiday after working all the summer. It need not be B's duty, for B may have had his holiday, and in that case there is a relevant difference. But if Kant misinterpreted the universality implied in right action, the necessity of universality, rightly interpreted, remains unaffected. Right action is universal in the sense that if it is right for A to perform a particular action it is also right for B, unless there is a relevant difference in B or his circumstances.

Right action, then, must be universal, but Kant was wrong in subordinating value (or goodness) to universality, although it is a misunderstanding of his position to censure the categorical imperative because it is 'formal.' Kant maintained explicitly that every act has its material or object.<sup>1</sup> He did not treat of willing in general, but of the willing of this or that. What he held was that the specifically moral element of an action lies in the fact that it was performed, not to attain some particular end, but because of its universality. But any action can be universalised. It is consistent, whether or not it is psychologically possible, to choose to act so as to bring about the maximum amount of misery to ourselves and others. Universality, then, is only one characteristic of a moral act, and value is the other. The act must be chosen

<sup>1</sup> Vide *Critique of Practical Reason*, Book I. chap. ii., 'Of the Concept of an Object of Pure Practical Reason.'

on account of its value as well as on account of its universality. This, however, is only a qualification, not a denial, of the 'fact of pure reason.' The universality, and probably the value also, imply the presence of reason, and consequently the logical grounds of Kant's argument remain as they were.

What, then, are these grounds? The fact of pure reason, Kant contends, means that pure reason determines action in time or, negatively, that there is *freedom*, since freedom implies the initiation of an action in time in a way that is not entirely explicable in terms of preceding events in time. Pure reason belongs to the intelligible world, it is the thing in itself, it is a noumenon. Events in time are phenomena belonging to the sensible world. How is it possible that the noumenal world or the world of pure reason, the 'intelligible character,' can determine the sensible, especially in view of two difficulties: (1) that cause and effect, strictly speaking, refer to phenomena only; and (2) that they hold universally of the phenomenal world, so that 'freedom,' in the sense defined above, seems impossible. How can these two worlds unite together in the mysterious bond of the moral judgment?

The *Critique of Pure Reason* had shown that phenomena are the only things which can be known as objects. The intelligible world can, therefore, never be known as an object. But the fact of freedom (to which we have already referred) makes the *Practical Reason* give a clue to the explanation of the world which the speculative reason by itself could not furnish. The speculative reason shows that freedom (or, positively, determination by the noumenal) is possible, but cannot show that it is actual. The fact of moral freedom, or of right action, does more than this. It shows that such determination is actual. The practical reason, therefore, has primacy over the theoretical, inasmuch as it goes further than

the speculative. It gives us fuller light upon the nature of the universe and, in particular, upon that portion of the universe which we call ourselves.

The argument is not an easy one to follow, and the principal difficulty attaching to it is the very perplexing problem of the precise sense in which the *possibility* of noumenal determination (acknowledged by the speculative reason) is relevant to particular cases of moral choice; and, clearly, the performance of a man's duty is always specific and determinate. Many of Kant's critics, indeed, maintain that the speculative reason (on Kant's definition of it) cannot logically admit even the possibility of freedom, but Kant's consistency, on this head, may be readily defended. While we cannot know *what* noumena are or, in other words, can never demonstrate the precise nature of the 'intelligible character,' we can know *that* they are. We can prove that phenomena are conditioned, and therefore know that they have conditions, although the intrinsic nature of these conditions baffles the understanding. And so we have not merely the *noumenon*, but the *causa noumenon*. Noumena are the *ground*<sup>1</sup> of phenomena, and determine the character of the existence of phenomena, although we do not, and could not, know the precise manner in which they do this. There is even a certain analogy between the determination of noumena and empirical causality. For the noumenon is the ground of the phenomenon, determining how it occurs. It is not strictly an antecedent, since it is not in time, but it is a condition. And, in this instance, one term at least is phenomenal, namely, that which is determined. In causation, in the strict sense, both cause and effect are phenomena.

It is possible, then (indeed we may have reason to believe), that the intelligible determines the phenomenal. We cannot tell *how* it does so, but we may

<sup>1</sup> Cf. *Critique of Judgment*, Bernard's translation, p. 39, note.

know *that* it does so. But it is much more difficult to see how we can know that this determination makes a special difference in particular cases. That the *whole* realm of phenomena (so far as it can be called a whole) should be determined by noumenal conditions does not affect particular causal laws. By their means we spell out phenomena and phenomena only: the noumenal determination is a general condition of all phenomenal connection and consequently is irrelevant to the special connections between special classes of phenomena. But when we come to freedom all seems changed. Kant has clearly particular cases in his mind;<sup>1</sup> he speaks of the act of rising from one's chair; and, as we have seen, no other sense of freedom would be relevant to morals. It would seem, then, that the specifically ethical facts upon which Kant bases his doctrine of the primacy of the practical reason are the weakest part of the foundation of his system. At the same time it is not unintelligible that, although all phenomena are determined by the intelligible, some phenomena should show this determination more clearly than others; and a man's acts in the concrete, so far as determined by considerations of duty, might possibly be of this kind.

Indeed, a possibility of this sort may obviate an objection which, doubtless, has already occurred to the reader. The objection is that there is never any meaning in saying that reason determines anything, determines it to act, that is to say, or causes any event to be what it is. An act of volition may cause a subsequent movement or train of thought, and this act may choose to follow the dictates of reason. But reason, in the sense of the intelligible connection, which is the ground of the choice, does not determine at all. The intelligible connection is there, whether we are aware of it or not, whether we choose it or not, and if it is a non-temporal connection, as Kant

<sup>1</sup> *Vide the Thesis of the Third Antinomy.*

supposes it to be, it cannot determine at one time rather than at another. But this is exactly what the actual volition does. The volition occurs in time and determines subsequent action. All causation, therefore, even that involved in right action, occurs at definite points in time and is therefore, on Kant's theory, phenomenal and not noumenal.

But, even granting this, it is clear that reason, on Kant's conception of right action, would determine such action in a way in which it does not determine other actions, *e.g.* the actions of a somnambulist. It is quite true that this intelligible connection, this universality, this reason, cannot be said to be a cause in the ordinary sense of the words. But Kant never maintained that it was a cause in the ordinary sense. On the other hand, reason does determine. If we choose a certain course because it is rational, then the rationality is a condition of our choice. The choice is a conscious choice and refers to the rationality of that which is chosen. Unless the choice referred to this rationality, and unless the rationality were the reason for the existence of the choice, that particular choice would not occur. There is sense, therefore, in maintaining that reason determines the choice of right action. And it is theoretically possible that such action could be explained by psychological rules of cause and effect, while at the same time it would be true that some particular psychical processes had also the quality of validity (ethical or speculative), and therefore were determined by reason.

I cannot see, however, that this admission proves the primacy of the practical reason. For, in this sense of the word, reason determines true belief just as surely as it determines right choice, and, indeed, the true belief that such and such an action can be universalised is a necessary pre-requisite of the right choice itself. The right choice may certainly determine our behaviour with respect to beings other than

ourselves. It will make a difference to the rest of the universe, and the true belief (apart, of course, from its expression) will not. But so far as the question of determination by reason goes, belief and choice are on the same level, and if there is any primacy of volition in the life of the self the reasons for that primacy are only those reasons for the primacy of the experience of activity which we discussed in the fifth chapter.

On the whole, then, Kant has failed to prove that the practical use of reason has primacy over the theoretical. If his aim were to discover indisputable evidence of the way in which reason determines the life of the self, he would find this evidence as clearly in true knowledge as in right action. And even if reason does appear in a purer form in right action than in right thinking, since reason dictates in morals while in knowledge it only interprets and is indissolubly linked with sense, that in itself would not prove the primacy of will. The fact of morality would give us more striking evidence than the fact of true knowledge, but it would not prove that the practical use of the reason is in fact constitutive in a sense in which the theoretical is not. It only proves that we cannot obtain our evidence as clearly in the latter case as in the former.

It is possible, however, that the *Critique of Judgment* throws further light on the question, from the point of view of will in the broad sense of purpose if not from the narrower one of ethical decision, and in view of Kant's relation to some of his successors, it is necessary to indicate, by means of quotations, the precise sense of the terms he uses. 'The Will, regarded as the faculty of desire, is, in fact, one of the many natural causes in the world, viz. that cause which acts in accordance with concepts. All that is represented as possible (or necessary) by means of a will, is called practically possible (or

necessary); as distinguished from the physical possibility or necessity of an effect, whose cause is not determined to causality by concepts (but in lifeless matter by mechanism and in animals by instinct). Here in respect of the practical it is left undetermined whether the concept which gives the rule to the causality of the will, is a natural concept or a concept of freedom.<sup>1</sup> Kant proceeds to argue that the two realms of Understanding and Reason (*i.e.* our knowledge of phenomena and of freedom) do not conflict with one another, but that each plays its distinctive part. In saying so he merely restates the conclusions of his previous *Metaphysic*, but he enters on new territory when he explains why, for the purposes of our knowledge, the two realms are not really one whole. 'That they do not constitute *one* realm, arises from this, that the natural concept represents its objects in intuition, not as things in themselves, but as mere phenomena; the concept of freedom, on the other hand, represents in its Object a thing in itself, but not in intuition.'<sup>2</sup> 'There must, therefore, be a ground of the *unity* of the supersensible, which lies at the basis of nature, with that which the concept of freedom practically contains; and the concept of this ground, although it does not attain either theoretically or practically to a knowledge of the same, and hence has no peculiar realm, nevertheless makes possible the transition from the mode of thought according to the principles of the one to that according to the principles of the other.'<sup>3</sup> The aim of the *Critique of Judgment* is to find the bridge which spans these two worlds.

Accordingly, it is easy to see, if we consider the question carefully, that the *Critique of Judgment*, despite its insistence upon teleology and purpose, can only throw light *indirectly* on the question of the

<sup>1</sup> *Critique of Judgment*, Bernard's translation, p. 7.

<sup>2</sup> *Ibid.* pp. 11, 12.

<sup>3</sup> *Ibid.* pp. 12, 13

primacy of will. It does not seek to prove that primacy but, on the contrary, presupposes it. The *causa noumenon*, freedom, does determine the *causa phenomenon*, mechanism and desire. The question is only how any relationship is possible between things so disparate as the objects of sense and the objects of reason? How can phenomenal nature be adapted to intelligible nature? And Kant's answer is that some of our experiences serve to show, subjectively at least, that such a harmony occurs in fact, and therefore it is reasonable to assume that the general characteristics of this subjective harmony may furnish a clue to the general question of the relation of the sensible to the supersensible. In aesthetic judgments the beauty of the object contemplated spells a harmony between the mere form of that object and our subjective faculties; and the purposiveness of nature, as seen especially in the adaptation of living things to their environment, seems analogous to the harmony between our purposes and our environment. Or we may put the question in another form. Granting that the practical reason has the primacy in the determination of the nature of the cosmos, have we any analogies in experience for this unity? Is there any intuition which is adequate in any respect to symbolise the whole? The answer is that some intuitions may be adequate in some particulars, though all are imperfect.

In his discussion of the organic realm Kant introduces many of the arguments which the writings of the neo-vitalists have made familiar to us, and he is much more acutely aware of the philosophical significance of his arguments than they usually are. To illustrate this I shall quote a passage of some length. 'In a watch one part is the instrument for moving the other parts, but the wheel is not the effective cause for the production of the others; no doubt one part is for the sake of the others, but it

does not exist by their means. . . . Hence a watch wheel does not produce other wheels, still less does one watch produce other watches, utilising foreign material for that purpose; hence it does not replace of itself parts of which it has been deprived, nor does it make good what is lacking in a first formation by the addition of the missing parts, nor if it has gone out of order does it repair itself—all of which, on the contrary, we may expect from organised nature. An organised being is, then, not a mere machine, for that has merely *moving* power, but it possesses in itself formative power of a self-propagating kind which it communicates to its materials though they have it not of themselves; it organises them, in fact, and this cannot be explained by the mere mechanical faculty of motion. We say of nature and its faculty in organised products far too little if we describe it as an analogon of art; for this suggests an artificer external to it. Much rather does it organise itself and its organised products in every species, no doubt after one general pattern but yet with suitable deviations, which self-preservation demands according to circumstances. We perhaps approach nearer to this inscrutable property, if we describe it as an analogon of life; but then we must either endow matter, as mere matter, with a property which contradicts its very being, or associate therewith an alien principle standing in communion with it (a soul). But in the latter case we must, if such a product is to be a natural product, either presuppose organised matter as the instrument of that soul, which does not make the soul a whit more comprehensible, or regard the soul as artificer of this structure, and so remove the product from (corporeal) nature. To speak strictly, then, the organisation of nature has in it nothing analogous to the causality we know.’<sup>1</sup>

<sup>1</sup> *Critique of Judgment*, Bernard’s translation, pp. 278-279.

The latter part of this quotation shows that Kant was fully aware that the aims of explanation are not served at all by postulating a teleological factor (or a soul) to explain the behaviour of living organisms, while the former part gives an admirable resumé of the type of argument which we have discussed in the preceding chapter. It is probable, I think, that the conclusions of the *Critique of Judgment* are too weak for the weight of evidence which he brought to bear. The difficulties of understanding the purposiveness of organic life—this purposiveness without a purpose—are so great that our intellects cannot cope with them. 'By the constitution and the principles of our cognitive faculty we can think of nature, in its purposive arrangements which have become known to us, *in no other way* than as the product of an Understanding to which it is subject.'<sup>1</sup> Purposiveness in Nature (which, for Kant, means adaptation), whether specific or general, can only be thought, he maintains, according to the effete principles of the argument from design, and these are necessarily inadequate. Hence the moral proof of the existence of God is ultimately the only one in which our reason can rest. There is no way, in the end, in which we can adequately represent to ourselves the determination of the sensible realm by the supersensible. The facts of morality are our only ground for believing in this determination, and we cannot, even in this case, know how the determination is realised. It follows therefore that the basis of the primacy of will, if there be such a basis or such a primacy, is to be found in the *Critique of Practical Reason* and not in the *Critique of Judgment*. I have introduced the question partly because it explains the historical origin of certain post-Kantian arguments in favour of the primacy of will, and partly because the arguments from purposiveness in nature, as we have

<sup>1</sup> *Critique of Judgment*, Bernard's translation, p. 369. (Italics mine.)

already seen in the preceding chapter, seem relevant to the issue. There is no warrant in Kant himself for supposing so. He is positive in maintaining that instinct at least is unconscious, and therefore no part of the self or of the will. As we have seen, however, his definitions of life and of desire seem very closely connected with his definition of will; and so it may be true that if Kant had fully appreciated the force of his own arguments he would have remodelled his position and accepted much which he in fact rejected. Schopenhauer, for instance, accuses the *Critique of Judgment*, not of error, but of incompleteness, and he criticises this incompleteness so tartly that we cannot help suspecting the presence of motives of personal jealousy. 'In the *Critique of the Teleological Judgment*, on account of the simplicity of the matter, we can recognise perhaps more than anywhere else Kant's rare talent of turning a thought this way and that way, and expressing it in a multitude of different ways, until out of it there grows a book.'<sup>1</sup> The work, he continues, is incomplete, especially because it fails to seek for a principle which 'would recognise both in the mechanical (according to law) and the apparently intentional effects of nature one and the same ultimate principle, which might serve as the more general ground of explanation of them both. Such a principle I hope I have given by establishing the will as a real thing in itself; and in accordance with it . . . especially in my work *On the Will in Nature*, the insight into the inner nature of the apparent design and of the harmony and agreement of the whole of nature has perhaps become clearer and deeper.'<sup>2</sup> Schopenhauer, like the Psalmist, is wiser than his teachers.

He was not, however, the only successor of Kant who believed in the primacy of will. An earlier, and

<sup>1</sup> *The World as Will and Idea*, English translation, vol. II, p. 156

<sup>2</sup> *Ibid.* pp. 158-159

a greater, was Fichte, who sought to show that the being of knowledge itself depends upon activity. His metaphysic, certainly, is very different from Schopenhauer's. Indeed, it seems a historical travesty to link their names together, since Schopenhauer rarely missed an opportunity for sneering at Fichte, and even at Fichte's personal honesty. But both contended for the primacy of will, although on quite diverse grounds, and therefore they agree verbally at all events. It need not surprise us if we find that some Voluntarists agree in no other way.

The best short statement of Fichte's views is found in his two introductions to the *Wissenschaftslehre*.<sup>1</sup> These views are especially interesting because they purport to be an exact philosophical interpretation of the self. Fichte did not mean the individual self. He did not mean, as Heine unkindly suggested, the particular ego called Johann Gottlieb Fichte. But the self (more accurately self-hood) must be the basis of every idealistic system; and every system which is not idealistic must fail inevitably, according to Fichte, because it cannot do justice to the reality of self. It soon finds itself forced to degrade the self to the *status* of an accident of the world. A philosophy which does not begin with the self can never reach it. A philosophy which begins with it can reach everything else. The *Ich an sich* must replace the *Ding an sich*; and the proof lies in the completion of the idealistic system.

Now the fundamental fact in the life of the self is the fact of freedom. It is true that we are conscious of a multitude of ideas, which are subject to the law of causality, and accompanied by the feeling of necessity. These we call Experience or, rather, *Erfahrung*. But it is the business of every philosophy to stand above experience in the sense of *Erfahrung*. It seeks to make *Erfahrung* intelligible, and exhibit its

<sup>1</sup> Published in 1797.

real ground. This ground is the absolute spontaneity and freedom of the self. 'Intelligence as such is aware of itself, and this vision of itself is directly united to everything which enters into it; and the nature of intelligence consists in this *unmediated* union of being and vision. Whatever is in intelligence and, in general, the very essence of intelligence, is to be *for* intelligence, and intelligence is only intelligence in so far as it is, in this way, *for itself*. I think this or the other object; but what is this object, and how do I appear to myself in this act of thinking? Only in one way: I bring some determinations of myself into prominence when the object is a mere fabrication; or they are present without my aid when the object is reality; and I am aware of thus bringing them forward or of this being. The objects are, in me only in so far as they enter into my self-cognition; self-cognition (*Zusehen*) and being are indivisibly united.'<sup>1</sup>

The original fact of the self—or rather, as we shall see in a moment, the original *act* thereof—is something still more ultimate than self-consciousness, in the sense of *Selbstbewusstsein*. The original datum is the return of the ego into itself. 'It is through this act first of all, and through it only, through an act upon an act which does not presuppose any anterior act, that the ego is *originally* for itself. It is only for the philosopher that it is present as a fact because he has already constructed the whole of experience.'<sup>2</sup> But what is the nature of this return upon itself? 'It is not conceptual knowledge, for that comes into being with the opposition to a not-self, and with the determination of the ego through this opposition. It is therefore mere intuition.'<sup>3</sup> This original act is called by Fichte *intellectual intuition*, and he regards it as the true and proper

<sup>1</sup> *Erste Einleitung*, p. 435

<sup>2</sup> *Zweite Einleitung*, p. 409

<sup>3</sup> *Ibid* p. 459.

interpretation of Kant's unity of apperception. But although the phrase suggests the primacy of intellect rather than that of will, Fichte considers his doctrine akin to the practical, not to the theoretical reason. The self is first of all an act, and by its action it comes to know. The modern reader will find an interesting parallel between Fichte and Bergson in this connection, not merely with regard to the general dependence of intellect upon activity but even with regard to details. Let us take this passage: 'I should like to know how those who in mentioning intellectual intuition adopt the fashionable view of its nature think of the consciousness of ethical laws, or how they could construct the notions of right or of virtue which they doubtless possess. According to them there are two kinds of *a priori* intuition, Time and Space, and without a doubt they construct these notions in Time, the form of the inner sense: but the notions are clearly, on their view, not Time itself but a certain filling of Time. But what is this filling of Time which underlies their construction? Nothing remains for them except space, and so their "right" must apparently be something rectangular and their virtue round like a circle, just as every concept of sense intuition which they construct (as for example a tree, or an animal, or the like) are nothing but limitations of space. Accordingly they cannot really think of right or virtue at all. What then is the (real) ground of their construction? If they pay attention they would see that it consists of action or of freedom.'<sup>1</sup>

In this passage there is an emphasis upon ethics which is not found in Bergson, but both agree in their insistence upon activity and in their denial that space by itself can be the true basis of reality. If Bergson is translated into terms of ethics, his argument reads as if it were Fichte's, a fact which

<sup>1</sup> *Zweite Einleitung*, p. 467.

is not surprising when we remember the relation of both of them to Kant. The doctrine that the intellect is especially concerned with space and time in the sense in which these are employed in physics depends, directly, as in Fichte, or indirectly, as probably in Bergson,<sup>1</sup> on that marriage between the categories and the forms of sensibility in the Understanding on which Kant insists so pertinaciously.

But life is wider than Ethics, and therefore, perhaps, Bergson is wiser than Fichte. Let us, however, consider Fichte's exposition of his fundamental position in fuller detail. As it is impossible to state Fichte's position more lucidly than Fichte himself, I shall content myself with giving two somewhat lengthy quotations from him:

'Now this whole procedure of the philosopher seems, to me at least, very feasible, very easy, very natural, and I can hardly see how it could appear otherwise to my readers, or how they could find anything strange or mysterious in it. It is to be hoped that each of them can think himself. It is to be hoped that he will become aware when he has come to this thought that he has come to something dependent upon his own activity, that is to say, that he will act. It is to be hoped that he will be able to distinguish this activity from that which he sets against himself when he considers objects outside him, and to find that in the latter the thinking and that which is thought are opposed to one another, so that his activity must go towards something different from himself, whereas in the former connection the thinking and that which is thought are one and the same, and therefore his activity returns inward upon itself. It is to be hoped that he will understand that, since the thought of himself arises in this way and in this way only, and because, as he finds, quite

<sup>1</sup> Cf. A. Lovejoy, 'Some Antecedents of the Philosophy of Bergson,' *Mind*, N.S. No. 88, pp. 465 ff.

a different thought arises when he thinks of an object over against him—he will find that the thought of himself is nothing else than the thought of this activity, and the word self nothing else than the sign thereof: that the self and an activity which returns upon itself are identical concepts. It is to be hoped that he will comprehend this, even if he presupposes only problematically, as transcendental idealism does, that all consciousness depends upon self-consciousness and is conditioned thereby. That is a presupposition which he must make in any case, as surely as he but turns an attentive glance upon himself and rises to the level at which he requires a philosophy; and its validity will be shown him categorically in philosophy itself through a complete deduction of the whole of experience from the possibility of self-consciousness. Accordingly he *must* think of this return upon himself as the presupposition of any other act of consciousness, as the condition thereof, or, which is the same thing, he must think that return upon itself as the most original act of the subjects. The reason is that there can be nothing for him that is not in his consciousness, for anything else in that consciousness is conditioned by this act itself, and therefore cannot condition it again in the same connection. It is, therefore, for him, and entirely unconditioned, and thus an absolute act. Accordingly this presupposition, and this thought of the self as originally conditioned through itself, are 'absolutely identical.'<sup>1</sup>

The second quotation, which is happily shorter, is chosen for the purpose of making this activity which returns upon itself a little more intelligible. Fichte himself admits that it is something too primitive (though not in a temporal sense) and too fundamental to be adequately explained by intellectual categories. These refer to an object, and thus presuppose a stage

<sup>1</sup> *Erste Einleitung*, pp. 461, 462.

of thought which is derived from, and therefore not identical with, the original activity of self-consciousness. The reader who is to understand Fichte must put himself freely into Fichte's point of view, and then the vision will be vouchsafed him. But certain descriptive phrases, however inadequate, and however cumbered by the implications of language, may set him upon the right track and stimulate him to exercise his freedom. The most telling passage occurs in the first introduction:

'Idealism explains, as has already been shown, the determinations of consciousness through the activity of intelligence. That on the theory is active and absolute, not passive. It could not be passive since it is the first and highest ground of what it postulates, and there is nothing anterior through whose influence it could be said to be passive. For the same reason no specific *being* or *existence* can be ascribed to this activity, since that is the result of an interplay of forces, and in the present instance there is nothing, and nothing can be supposed, with which the intelligence can be supposed to interact. Intelligence is for idealism a *doing* (*Thun*) and absolutely nothing more. It should not even be called an active thing (*ein Thätiges*) since this latter expression implies a reference to some species of existence in which the activity dwells. . . . Accordingly this is the presupposition of idealism. Intelligence acts, but, because of its own specific nature, can only act in a determinate way, and if, abstracting from action, we consider the necessary manner of acting, we may fittingly call it the law of activity. Therefore there are necessary laws of intelligence.'<sup>1</sup>

Fichte's idealism, then, begins with an analysis of the *Ich an sich*, the fundamental act which lies at the basis of the intellect as we usually mean and intend

<sup>1</sup> *Erste Einleitung*, pp. 440-441

it. Whether the foundation is strong enough for the superstructure is not our present concern. Fichte may have deduced incorrectly from true premises; our problem here is to examine their truth. The relation of the *Ich an sich* to your self or mine is certainly a puzzling problem: so, for that matter, is Fichte's account of the *Anstoss*.<sup>1</sup> Our selves, in particular, seem to be born and to die in time and, therefore, they are, in a sense, passive. But even from the psychological standpoint they are also spontaneous, and we may grant, at least for the sake of argument, that Fichte's analysis, if it is true, holds of any particular self. He maintains, then, that a 'free act' is the basis of the *Ich an sich*: that this act pertains to the practical reason, which is consequently the basis of the speculative. Let us examine this contention.

We may admit that the speculative reason, or, in other words, conceptual knowledge implies a free act, whether this act be interpreted as the *prius* of the conceptual knowledge, or as part of it. It is free in the only legitimate sense of freedom. So far as we know, the way towards these acts is paved by preceding events, but the acts may, none the less, initiate a new series. Intellect is partly tied down to its object, but only in part. If it be correct to say that a free act, an 'intellectual intuition,' is at the basis of intellect, then Fichte is right in asserting this characteristic of freedom. The act is not a retainer to anything else. When it exists, it exists *for* itself, in its own right.

I confess that I do not see that there is any warrant for going behind this element in knowledge. Knowledge does not exist merely in fee of the object. It refers to the object freely. Fichte, on the contrary,

<sup>1</sup> The *Anstoss* (shock or collision) is the negative principle which, according to Fichte, makes the original absolute act recoil upon itself, and so produce determinate knowledge.

maintains that knowledge implies the relation between subject and object, and that this logically implies an *Ich an sich* behind, though not below, this distinction. That is the free act returning on its self which *posits* the object. The act is a *prius* even of the existence of the object, so that being is logically subsequent to activity. Omitting the second part of the contention for the moment, let us ask whether the first part really implies the primacy of the practical reason.

It clearly does not have this implication if the 'practical reason' be interpreted in Kant's sense, which refers chiefly to deliberate choice. We can only choose in this way if we know what we are about, and therefore Fichte's act could not *will* to let itself go unless it knew where it intended to go. Nor would any other sense of will allow him a better chance of success. In any sense in which will is an experience it refers to an object, and therefore requires an object just as much as the intellect does. If then there is primacy of will there is no ground, on Fichte's premises, for believing that the will, as we mean and intend it, or as an experience, has this primacy, and it is surely gratuitous to add a metaphysical ambiguity to the psychological ones which already hamper clear thinking. And there are certainly no grounds in Fichte's argument for believing in *ethical* idealism. Freedom, in the sense in which we know it, is a characteristic of the intellect as much as of the will. If a further free act, in Fichte's sense, be logically implied, then that act is the basis both of intellect and will. It is distinct from, and behind, both knowledge and will, and is not itself either of them.

The argument that activity is the basis of existence, and prior to it, falls under the same condemnation. If Fichte is right, then activity is prior to the existence of the self, but not activity as an experience, nor will as an experience; and it is hard to see what other sense of activity could be significant. It is

tempting to hold that to be is to be active, but that need only mean that nothing can exist unless it does something, a statement which is very likely true. True, the scholastic maxim '*operari sequitur esse*' need not be true in point of time, or in point of logic. We have no reason to suppose that things first exist, and then begin to move; and although the motion of anything seems logically to imply its existence, there is no good ground for supposing that process is derivative upon existence. Process may be as fundamental, as necessary, and as universal as existence, and the extension of existence and process may necessarily be one and the same. Fichte's argument, however, is on a different footing. His doctrine would seem to be that the subject is the logical *prius* of the subject-object relation. Students of philosophy will remember the *impasse* into which he was led in his attempt to provide further explanation.

In passing from Fichte to Schopenhauer, we part company with ethics and come nearer to biology. The atmosphere is still Kantian in a manner, for the will is held to be the thing in itself, and, as we have seen, Schopenhauer was jealous of the way in which the *Critique of Judgment* encroached on biology and the analogies that can be drawn therefrom. For Schopenhauer the primacy of will is unequivocal because it is the thing in itself; the intellect must assume a secondary place. But he interprets the will which lies at the basis of nature with a laxity which makes it almost, if not quite, unintelligible. It appears in our consciousness as an impulse and a striving towards life, and thus it covers all experiences of activity. It also appears in instinct, although there it is unconscious of its end. When a short man marries a tall girl he does not know that the explanation lies in nature striving through him to preserve the average. And the will

also appears in inanimate nature. The compass needle points to the pole because its action, like everything else, is the manifestation of will.

Indeed, Schopenhauer's most consistent position—and he is never very consistent—is that the will is in itself unconscious, but that the experience of striving comes nearest to revealing its true nature: 'The will, as the thing in itself, constitutes the inner, true, and indestructible nature of man: in itself, however, it is unconscious. For consciousness is conditioned by the intellect, and the intellect is a mere accident of our being. It is a function of the brain. The intellect is the secondary phenomenon; the organism is the primary phenomenon . . . the will alone is the thing in itself.' Schopenhauer's argument, I think, may be stated somewhat as follows: There must be a thing in itself, and the intellect is incapable of appreciating its nature. On the other hand, there is every reason to believe that this nature is immediately revealed in will, and this general thesis can be made more convincing by the proof that, at least in self-consciousness, the will has primacy.

The first truth to realise is that the world as presented to us is idea and our idea. It appears to us under the conditions of our consciousness, and we are immediately aware of it in the form of sensation, *i.e.* as a modification of our own bodies. But sensation is not enough. We inevitably go farther and by means of the category of cause, with its implications of time and space, build a world for ourselves. We do so in and through reason, and without reason we could not even have precepts. But reason is feminine in nature; it can only give after it has received, and the material on which it works is sensation. Hence the world as idea is subjective. It is not the real world. Mathematics and natural philosophy cannot raise us from the clay of ideas.

But we cannot be satisfied with this realm of ideas: we want more than a world of shadows; and the laws of cause and effect and the other appurtenances of reason cannot bring us nearer the heart of things. They show us a crowd of strangers each introducing the other as a near relative. We want to know how we stand to the whole company. And we want to know, if we can, the real soul of each member of the company. The laws of nature are derivative. They must depend upon an inner spring of nature, and the intellect can only recognise the laws: the inner spring is beyond its ken. This demand for something more than idea is rooted in our lives. We are living beings, and yet we appear to ourselves under the guise of ideas. We know our bodies as idea, and can read their changes according to laws of cause and effect. But we are not restricted to the way of ideas in perceiving these changes. Our bodies are also given to us as will, and thus we have the clue to the inner mechanism of the body. We are really will: our bodies are nothing but the will become visible: and voluntary action is only the visible aspect of an individual act of will. 'Phenomenal existence is idea and nothing more. All idea, of whatever kind it may be, all object, is phenomenal existence, but the will alone is a thing in itself. As such it is throughout, not idea, but *toto genere* different from it; it is that of which all idea, all object, is the phenomenal appearance, the visibility, the objectification. It is the inmost nature, the kernel of every particular being, and also of the whole. It appears in every blind force of nature, and also in the preconsidered action of man; and the great difference between these two is merely in the degree of the manifestation, not in the nature of that which manifests itself.'<sup>1</sup>

The question is, of course, what right Schopenhauer

<sup>1</sup> *The World as Will and Idea*, English translation, vol. i. pp. 142, 143.

has to this identification of the will with the thing in itself. On one point he is clear. The will is not merely inferred. It is not an  $x$ , otherwise unknown, which is required to fulfil certain conditions: 'The word will, which, like a magic spell, discloses to us the inmost being of everything in nature, is by no means an unknown quantity, something arrived at only by inference, but is fully and immediately comprehended, and is so familiar to us that we know and understand what will is far better than anything else.'<sup>1</sup> It is the *prius* even of force: for force is only an  $x$  inferred as the correlate of causation. With will it is otherwise; will is the true *principium individuationis*, in itself one and indivisible, lying outside space and time and cause. Each man feels himself free but must think himself as determined. The reason is that he *feels* himself to be will, and *thinks* himself as phenomenon.

Schopenhauer insists, then, that we do understand the will, but not by the way of ideas; and it follows that there is no theoretical difficulty in maintaining both that we know will as the thing in itself, and that the intellect is acquainted with phenomena only; for the source of our knowledge is different. This is the road of escape which is always sought by those who adopt a view like Schopenhauer's, and it is a very perilous one; the intellect and the intellect alone can judge whether the will, however known, is the thing in itself and the ground of phenomena. Grant that we are aware of ourselves as will in a quite specific way, and it is still necessary to explain what right we have to believe that will is the ground of phenomena. If we define intellect, from the start, as that which employs the categories of space and time and cause, in the mechanical sense, and employs no others, then, no doubt, we can proceed to depreciate the intellectual powers. But why should

<sup>1</sup> *The World as Will and Idea*, English translation, vol. 1. p. 144.

we so define it? We are manufacturing difficulties by adopting arbitrary restrictions. Moreover, except upon this arbitrary assumption, the fabric of Schopenhauer's system melts away. It is true that we know ourselves as idea or presentation, *i.e.* we have intellectual awareness of ourselves; and if the intellect is necessarily restricted to the forms of space and time conjointly, then our bodies are the only sort of ideas which could manifest ourselves. But we have seen reason to maintain that our bodies are not parts of ourselves, and hence that the intellect can not be restricted in the way Schopenhauer maintains. Moreover, how can it be maintained universally that the will is objectified in the body? As Fichte would say, right would be square and virtue circular. If the grounds for our action are ethical how can they, as such, be objectified in space? And again, it is clear that Schopenhauer's doctrine involves an immense extension of the data supplied by consciousness. He would be the first to assert that much of the objectification of will in our bodies is not an objectification of conscious will. It is will only by analogy, and we have seen in the previous chapter how weak this analogy is.

It is unnecessary to pursue this line of criticism further. If our previous argument is sound, Schopenhauer has no right to assert either that we know immediately and unambiguously what will is, or that it is our real nature and explains our life and behaviour. If it is a magic spell, then the task of philosophy is to purge this spell of its magic. The will is not a revelation from heaven for the express benefit of perplexed metaphysicians. But it still remains possible that the will has the primacy in the life of the self and that Schopenhauer's assertions are true though these particular reasons for them are faulty; and he makes other attempts to show that the will as such is primary, and the intellect necessarily

secondary. It may be, then, that we shall be able to find valid arguments on this head in Schopenhauer's system, although they are absent in the general argument for that system. An appendix to the second book of *The World as Will and Idea* is devoted to the question of the primacy of will in self-consciousness, and we shall turn to it in our search for independent arguments. It is pleasing to note that Schopenhauer begins by saying that his arguments in this appendix are more important for the explanation of the inner man than a multitude of systematic treatises on psychology.

There are twelve separate arguments mentioned, but some of them are not really independent of those we have already considered. The second of the twelve *e.g.* maintains that will is common to man and the animals, while intellect, in any developed sense, is man's exclusive possession. And the inference which is presumed to follow is that the increasing complication of the human organism creates a multitude of wants which compel the development of intellect in order that they may be supplied. This, so far from being an independent proof of the primacy of will, is really an answer to a somewhat serious objection, namely, the importance, apparently the independent importance, of the intellect. The reply is consistent enough provided the primacy of will has been proved, but otherwise it is impotent. Or, again, Schopenhauer maintains that a man's intellect slumbers and is weary, while his will is ceaseless and untiring. That is not true of will as a psychical experience, for, in that sense, it, too, may become nerveless and exhausted. The argument is plausible only if the previous metaphysic, and its interpretation of will, is accepted.

Then, again, there are similes which are nothing more. The intelligence, we are told, is like the sun. It cannot illumine until its rays are reflected by

some object. There are, however, some independent arguments which require more than a passing mention, and I shall select two of them because they seem to me to be most important.

The first of these states that the intellect is only the tool of the will. It appears to guide, but in reality is determined by the will: 'To believe that knowledge really and fundamentally determines the will is like believing that the lantern which a man carries by night is the *primum mobile* of his steps.'<sup>1</sup> The will sets the goal, the intellect only deciphers means. The intellect in a way supplies motives to the will, but does not penetrate into the secret workshops of its purposes. It is not informed of all the facts. Consider how some unexpected joy or some momentary success changes the whole current of our thoughts: consider how the 'native hue of resolution' compels the intellect to proceed: consider how emotion and excitement, disturbing influences from the will, stir the calm pool of intellect till it is lost in a very whirlpool of uncertainty. The reality of will presses home on us. When and so far as the intellect attains its calm impartiality we cease to be real beings. We are like the gods on Olympus. When we descend into the arena of conflict we become real. If we are wounded, we bleed.

This type of argument is the strongest that can be adduced, and it is on it that the consensus of psychologists to which I have referred in an earlier chapter, principally rests. It does not prove the primacy of will, because it refers equally to the primacy of feeling. Schopenhauer's magic spell is not subtle enough to distinguish the two. The argument goes to prove that the kernel of the self is to be found in feeling and endeavour. In these experiences we are most real and are most tensely aware of our personality. Hence these experiences are the most real part of the

<sup>1</sup> *The World as Will and Idea*, English translation, vol. ii. p. 440.

self. The self exists, and its existence is brought home to us most prominently in these experiences. They are, therefore, its essence.

It is true that in our feelings and actions we are essentially parts of the world. The strongest feelings and the most insistent actions are bound up with our bodies, and these in turn are in direct contact with their environment. The intellect, on the contrary, may entertain plans which are bare possibilities, and consider universals which cannot be shown to be actual through the avenues of sense. But that is too little to establish the argument. If the contention be that the intellect is a relatively unimportant part of the life of most persons, then we may, perhaps, grant its truth. Few men devote much time to speculation, and few are capable of profiting greatly thereby. But if it is intended to decry cognition to the profit of feeling and endeavour, then surely it fails of its aim completely. Let us grant that we seem to be most real when we seem to deal with actualities. Even then perception has as good a claim as feeling or endeavour to deal with them, and the cognitive acts of perception are as truly parts of ourselves as acts of feeling and desire. The aggressive character of perceptions, which Hume mistakenly called their vivacity, is as much a criterion of reality as the feelings and strivings connected therewith. And Schopenhauer's examples do not really affect the argument. An unexpected joy changes the course of our thoughts. It changes equally the course of our activities and our feelings, and we have no ground for believing that the joy is the sole agent in the case. It is joy connected with some new piece of information, and of this we must be cognitively aware. Cognition is essential to the presence of feeling or endeavour. Why, then, maintain that their importance is the greater?

Moreover, our activities may be directed towards

the contemplation of possibilities, and feeling must be connected with this process. These feelings and these activities may be less strong and less frequent than others, but they are not therefore less real. And it is an error to suppose that the thought about a possibility is less real than the thought about what is actual. Let us suppose that philosophers and poets contemplate nothing but possibilities. It does not follow that the thoughts of Spinoza or Wordsworth were less real than those of Napoleon, or that they were not selves as well as he. These grounds, I think, are sufficient to reject the argument. Cognition is as essential to the self as conation or feeling. Unless the three elements work together they will not work at all, and it is futile to assign the primacy to any one of them. The union and the interdependence is so close that it is a mistake even to attempt to assign them varying degrees of importance. In an organism the brain is possibly more important than the lungs, although both are essential. But the unity of psychical processes is closer than that of the parts of an organism.

Another argument is also of some importance. It maintains that in imputing blame to ourselves we are so far from reproaching ourselves with defects of intellect that we seek to show the presence of these as palliations of our offence. We impute our crime to ignorance or want of reflection, and in doing so consider that we have relieved ourselves, at least in part, of our responsibility; and this fact goes to show that the will is the really significant part of a man, and is considered to be so by himself and by others. Moral excellences, a man's character, are his real self. Excellences of intellect are gifts of nature or the gods. They may be rare and precious, but they are extrinsic to the man.

This argument, however, is so far from proving the conclusion it desires that it tells at least equally

in the opposite direction. When we estimate conduct, then, no doubt, our actions only are relevant. Unless we have chosen the action we should rightly maintain that we are not responsible. But in the instance in question the choice is not in dispute. The man who acted in ignorance, or after insufficient reflection, does not deny that he chose to do as he did. What he maintains is that he had insufficient intellectual data for guiding that choice. He did not know enough, he did not take time enough to reflect. Had he known more, he would have acted otherwise. He admits in other words that knowledge is necessarily the guide to action. He would admit, if pressed, that action is ethically unjustifiable, unless it is informed by knowledge. It does not follow, therefore, that the choice is more fundamental than the knowledge. He is responsible for the choice on the basis of knowledge. The fact that he is capable of guiding his choice by his knowledge is as clearly a part of himself as the choice itself is. True, he may urge that he is not responsible, because he could not have known this or the other circumstance. That is not a matter for himself alone. It may be due to chance. But just as knowledge requires an object, so responsible choice requires knowledge, and the argument, therefore, falls.

It is impossible to leave this part of our subject without considering the theory of one who is often proclaimed the chief of the Voluntarists, and has even been called the greatest of the pragmatists. M. Bergson's conclusions *seem* not unlike Schopenhauer's. Both insist that action is the fundamental reality of the self and the world. Both depreciate the intellect, and represent it as a tool which, however useful, is incapable of coming into touch with reality. But while there are broad resemblances between Bergson's conclusions and those of 'Die Welt als Wille und Vorstellung,' it is doubtful whether there is much

more than verbal agreement in the end. And it is also doubtful whether Bergson is, strictly speaking, a voluntarist. He seeks to dig more deeply into the self than ordinary psychological analysis can, and he finds, as a result of his excavations, something which is perhaps, least inadequately, described by the word activity. But whatever this is, it is not conation, and it is not volition in the ordinary meaning of those words. It is something almost impalpable from its very simplicity, and if we try to translate it into ordinary psychological terms, it is as much cognition as anything else. Bergson's attempt is not to reduce cognition to will but to explain how each of them implies, in the last analysis, something much more fundamental than either. The intellect, indeed, is inadequate, and must be supplemented by intuition, but intuition is very far from being mere striving or resolve.

In proof of this position it is enough to give an account of Bergson's analysis of pure perception in *Matière et mémoire*. That is his most important book, up to the present, and it lays the foundations of his further metaphysics. Pure perception, indeed, is not itself mind, since mind cannot exist without pure memory also. But it is a fundamental element in the analysis of mind, and the roots of Bergson's voluntarism, if they exist, are to be found in it.

Bergson, like many another philosopher before him, sets out from the problem of body and mind. The fundamental error, he thinks, is to suppose that these two are duplicates, one of another, and it is irrelevant in what precise form this duplication is held to exist. Epiphenomenalistic parallelism, *e.g.* which asserts that an inert series of sensations somehow accompanies and corresponds to a series of changes in the brain, is an uncouth miracle, and the dualism of common sense inevitably tends to be interpreted in the same way. The fact of the exist-

ence of the conscious series, not to mention its function, becomes absolutely unintelligible. For idealism on the other hand (and it is plain that Bergson has the English empiricists chiefly in mind<sup>1</sup>) it is impossible to explain how the inner circle of subjective ideas can ever lead beyond itself. Ideas there are, but what of the world?

To overcome these difficulties, he thinks it necessary to make a more penetrating analysis than has yet been made. If we consider our bodies, from the scientific point of view, we find that they exist, *along with* other physical things, in space and time. They are not separated from other things, but always interact with them. They are, in fact, centres of action. There is no mystery here. The connection between sensory and motor nerves is the fundamental fact for physiology, whether in respect to the cortex, or to the centres of automatic reflexes. The efferent nerves are in touch with the environment: their being is to be a motor response to the environment: and the being of the afferent nerves is to lead up to, and to issue in, this response. The characteristic function of the body is really to be a centre of action which *selects*. The end-organ, and the nerves connected with it, do not react indifferently to all stimuli, as protoplasm does to all save magnetism. The end-organ reacts primarily to its *adequate* stimulus, the eye to light, the ear to sound.

Now let us try to set aside the meaningless duplication of ideas on the one hand, and a physical world in space and time on the other. Let us make a concession to idealism. All reality is akin to consciousness. There are not two realms, one of conscious presentations, and the other of physical things. The ultimate reality is something which partakes of both, but is neither. We ought to suppose that space and time, and the matter composing

<sup>1</sup> He is also thinking of Kant in a lesser degree.

them, are distorted constructions of the intellect, for they are constructions from selected percepts and have lost the fundamental continuity of the real. What exists, in the end, is an indivisible continuum. We may call it an 'image' in the effort to get a neutral name. Without a doubt the material universe itself, defined as the totality of *images*, is a kind of consciousness which interpenetrates in the way we find in the depth of our own souls. Space and time, and that which is supposed to occupy them, cannot attain this union. If, then, we reinterpret the facts of physiology from this point of view, we find nothing inexplicable, and no duplication. Since the ultimate reality is something anterior to space and time in the usual sense, we are not, of course, concerned with the body in precisely the sense of the physiologist. Let us, then, suppose the body contracted, as it were, to a mathematical point, and all is plain. This point is a centre of action. Perception is a selection from the continuum. It *must* issue in action, and may be called '*action virtuelle*,' a sketch of action issuing in action. These terms are ambiguous only if we read into them an illegitimate intellectual construction. The fundamental reality is so simple that it escapes the intellect: 'In representing reality to ourselves in this way, we do nothing but return to the naïve conviction of common sense. Every one of us began by believing that we enter into the object itself, that we perceive it in itself, and not in us.'<sup>1</sup>

• The obvious objection to this analysis would run somewhat as follows. Bergson has tried to find something more ultimate than mind or body, and in so doing he has succeeded in obliterating the distinctive meaning of mind. What is more, he cannot invest it with that meaning any more. He is like the magician in the fable. He has made the well yield water, but he has no spell to check the flow when he

<sup>1</sup> *Matière et mémoire*, pp. 31, 32.

desires. If we keep to introspection, and there is no good reason for doubting its authority, then we cannot get behind the fact that there is all the difference in the world between action and the entertainment or the consciousness of a plan of action. The latter may issue in the former. Often, perhaps, it seems to have no other office. But it is a distinct element which cannot be reduced to action. To say that perception, in any sense, is virtual action, is a *contradictio in adiecto* if it implies that perception is action, and a harmless platitude if it only means that perception issues in motor reaction.

Such an objection is always open to the charge of *ignoratio elenchi*. Bergson has arrived at a point of view more ultimate than that of the critic, and so he is proof against all missiles save those of his own kind. And this, I suppose, is the attitude which a defender of Bergson would adopt. 'This method of treating perception,' Mr. Lindsay says, 'naturally raises the objection that we are ignoring the element of consciousness and the fundamental difference between consciousness and action. But pure perception is not regarded as something existing by itself, but rather as one of the aspects of all intelligent action, and this method of treatment presupposes all along that intelligent action is a whole in which the two elements of consciousness (which implies time and memory) and action (which implies a system of movements in space) can be distinguished, each implying the other.'<sup>1</sup> This reply hardly meets the point that cognition, as an experience, is not activity, as an experience, and that the one cannot be reduced to the other. And

\* I do not see how that point can be met. Bergson may have arrived at something common to all experiences and more ultimate than any particular kind of experience, but, if so, he is going behind will, as well as going behind cognition.

<sup>1</sup> *The Philosophy of Bergson*, pp. 166, 167.

It is plain, indeed, that Bergson's concession to 'idealism' involves this implication. He is thinking of the duplication between presentations (in Hume's sense or Kant's) and the physical world (in the current scientific sense), and he abolishes the duplication by insisting that the ultimate reality is simpler than either and partakes of the nature of both. It may be so, but, unfortunately, neither of these series is mind at all. Both of them are objects for mind, an image or presentation as much as a physical thing; and if the two had a common basis and were fundamentally akin we should still be as far away from mind as ever. Mind can never be represented as a series of sensations or images: it refers to these as to other objects. Accordingly, Bergson's analysis either omits mind altogether, or else presupposes it all the time. The distinction between presentations and the physical world is only part of the problem of mind and body, and if the more ultimate problem is still an enigma it does not become less of an enigma by being overlooked.

It is doubtful, therefore, whether Bergson's theory commits him to Voluntarism, since he arrives at something far deeper than conscious will as a result of his attempt to penetrate into the depths of the soul. On the other hand, the broad outlines of his general theory are certainly construed according to the tenets of Voluntarism, as is especially evident in the argument of *L'Évolution créatrice*. *Homo sapiens* is *homo faber*, and he is *homo faber* because, in the last resort, he is *homo agens*. The human intellect arises from a more ultimate matrix, whose nature is revealed in movement and action, and the intellect falls under the same condemnation as its constructions of physical space and time. The critic, however, may be permitted to doubt whether these extreme consequences necessarily follow from the fundamental basis of the theory. That the develop

ment of the intellect depends upon the necessity for supplying practical needs, and that these, in their turn, depend upon an impulse to be up and doing, is, as we have seen, incapable of proving that the intellect is the slave of practice *now*. And the grounds for Bergson's depreciation of the intellect seem insufficient in other ways. The fundamental continuum, and the interpenetration of the elements of mental life, on which he insists with so much force and truth, is certainly revealed in action, but is also revealed in perception and, according to Bergson's own theory, in everything that is covered by the term *intuition*. But intuition is not mere action, just as pure perception is not action, and the primacy of will cannot therefore be proved from the fact, if fact it be, that action reveals the nerve of the soul most profoundly. Moreover it is, to say the least, a moot point whether the intellect is really incapable of interpreting the fundamental continuity of the real. The intellect cannot do more than interpret. It cannot perceive or intuite this continuity. But it may describe the continuity in terms which imply no contradiction, and have both relevance and meaning. It is very unfortunate that Bergson should have devoted so much labour to his destructive criticism of intellectual attempts at the description of continuity, because this criticism remains the weakest point in his argument.<sup>1</sup> He does not meet the arguments of modern mathematicians and logicians on their own ground, and consequently the arrows of his argument, if they can fly, cannot pierce.

<sup>1</sup> The proof of these dogmatic statements would, of course, require a volume. I may refer the reader to Mr Russell's pamphlet, entitled *The Philosophy of Bergson* (which contains a reply by Mr. H. Wildon Carr), in order to show that Bergson and his opponents are entirely at cross-purposes, and that his arguments do not meet their contention. It is plain that no sane theory claims that the intellect is its object, but only that it is capable of interpreting that object. And it is an obvious inference from this fact that any criticism of the intellect which depends on the assertion that it is *static* and not *dynamic*, is wholly inept, since the interpretation of movement need not itself move. Unfortunately this criticism seems a popular, but not inexact, formula for much that Bergson says.

The aim of this and the two preceding chapters has been to establish a very simple conclusion. The question is whether will, in the broadest or the narrowest sense, is the essence of the self, and the discussion has proceeded on the assumption that the question is one of the interpretation of experiences known through introspection. The first step, therefore, is to discover the precise nature of the relevant experiences, and the second to interpret the meaning and function which can be assigned to them. When the first step has been taken, it is plain, without further argument, that the experiences of will or activity are not the only experiences, and that the self cannot be said to consist of these alone; nor can such experiences be reduced to any other experiences. When, in the second place, we come to interpret these experiences, we find that there is no good reason for maintaining that they have a primacy over other experiences. All are necessary, and none of the principal classes of experiences seems to be more necessary than the others. This interpretation has necessarily involved the discussion of many theories. Many attempts have been made to extend the interpretation of will so far by analogy that it seems to be the basis not only of the self, but of the whole realm of organic existence. The arguments in favour of neo-vitalism are the most important of these attempts; and detailed consideration shows that the analogy on which they are founded is extended too far to permit of real explanation. And, again, it has been held that will is the revelation of some more ultimate cosmic principle from which the self draws its life in the same way as all else. I have not tried to deny that there are such ultimate principles, whether Kant, or Fichte, or Schopenhauer or Bergson describes them best. But these, if they exist, have no closer kinship with will than with cognition or feeling.

•                      .

## CHAPTER VIII

### THE SELF AS KNOWER

SINCE an essential part of the argument in the preceding chapters was a vindication of the importance of cognition in the economy of self-hood, it may seem unnecessary to devote a chapter to the self as knower. Knowledge is included in cognition, and if the whole be justified, so is the part. Cognition, as we have seen, is co-equal with the other elements of experience. It cannot be reduced to the others nor shown to be merely a necessary adjunct of them. In short, the self is a republic, at least at the level at which we are considering it now. Nothing seems to remain, therefore, save perhaps the further analysis of cognition, the more precise statement of its place and function, or the criticism of any theories of cognition which imply that it, in its turn, has greater privileges than other elements of the self. These questions, important as they are, have also been discussed incidentally. In the attempt to discover what an experience is, we argued principally from the analysis of cognition. We saw that it is an act referring to an object, we discussed the meaning of the word 'object'; we saw that cognition has various 'qualities'<sup>1</sup> (including such different experiences as those of entertaining a meaning, asserting it, and the like), and that it is a general term implying not merely intellectual awareness, but the acts of perceiving, sensing, *et id*

<sup>1</sup> In the technical sense explained on p. 30.

*genus omne*. Similarly the function of cognition has been explained. It is the guide of conscious life, whether that be willing, acting, feeling, or further thinking. And the third point has also been answered by implication. Arguments for the primacy of feeling or will are, for the most part, indications of a revolt against the primacy of cognition, and the measure of truth they contain is sufficient to refute any arrogant assertions of the right to a cognitive despotism.

There is another reason why it may seem superfluous to explain, or vindicate, the importance of cognitive experiences. Cognition, after all, has pride of place in nearly every account of mind which is written from the psychological standpoint. Psychological text-books treat principally of sensation, perception, ideation, conception, even if the writer believes conation to be still more fundamental. Indeed the term 'consciousness' itself is too often used as if it meant cognition only, and that is why so many writers assume the existence of the element of cognition when they try to reduce consciousness to conation. They are speaking, they say, of *conscious* striving, and they interpret the word 'conscious' as if it meant cognitive. In the preceding argument I have endeavoured to avoid this mistake. All experiences are conscious (or subconscious), but not all are cognitive. The other classes of experience are indissolubly linked with cognition, but they are also distinct from it.

Accordingly the discussion in the present chapter must follow along somewhat different lines from that in the preceding ones. Of course, there are innumerable problems of cognition, but the fact that they are so many makes it impossible to consider them all. We must select those which are, on the one hand, distinctively connected with the general problem of the constitution of the self, and, on the other hand,

directly dependent on the analysis of the experiences of knowing. The most important problem, from this double point of view, is that of the sense in which knowledge implies a knower. In one sense of the words, the answer to this problem demands the whole argument of the concluding chapters of this enquiry, since it is the problem of the soul; but certain features of the problem, and certain arguments which insist upon these features, ought to be mentioned in this place. At this stage of our enquiry we are concerned with the way in which the analysis of distinctive kinds of experiences throws light upon the general economy of the self, and so we must examine the doctrine that knowledge implies a knower on account of certain distinctive characteristics of the nature of knowledge as a specific kind of experience, and that a direct analysis of knowledge reveals the fact plainly. There is no precise parallel to this type of argument in the case of the other classes of experiences, and consequently our enquiry must adapt itself to this difference in the subject-matter. Before proceeding to this problem, however, it is expedient to take stock of our previous conclusions, and it is necessary to consider the question of the *content* belonging to an act of cognition in somewhat fuller detail than has been attempted hitherto.

The discussion of the Self as Feeling, and the Self as Will, was provisional in several respects. In the first place, it was conducted, so far as possible, in abstraction from the question of the unity and continuity of the self. In the second place, it was concerned only with the *experiences* of feeling and will, or, in other words, with what has been called the 'empirical self'. The phrase is not a happy one in some respects; for it savours of question-begging. It is correlative to the 'pure ego,' and perhaps neither the 'empirical' nor the 'pure' ego can exist

separately. And, conceivably, they cannot exist together, since a dualism of this kind may be false in fact. In any case, the question of the relation of the 'pure ego' to the 'empirical self' has not yet been discussed because it is the culmination of this enquiry; but a provisional abstraction of the one from the other may be readily justified. We are bound to begin by considering 'psychology without a soul' in the legitimate sense of the phrase which implies merely the provisional neglect of the problem of the soul, in so far as that term is interpreted to mean that an ego other than experiences must exist. We have seen no reason, hitherto, for denying that experiences are really parts of the self, and, in any case, the interpretation of experiences is the only road by which it is possible to arrive at an adequate comprehension of the being of the self. Accordingly we must begin with the empirical self, although the problem of its ultimate reality remains.

A further presupposition of the argument is that experiences are *sui generis*, and afford a fixed starting-point which cannot, so to speak, be undermined. They are known primarily through introspection, and introspection shows them to be a distinct and peculiar type of being. Let us scan this statement a little more narrowly. Experiences are not *qualities* of anything else, *e.g.* of the body. They may depend on the body, but their distinctive features are not bodily features. There is an attractive simplicity in the view that consciousness, or something akin to it, is a quality of all existence, although the quality may have very different degrees of development; but the temptation to regard it in this way must be strenuously resisted. It is clear on reflection that an act of cognition, or an act of resolve, is not a quality of, let us say, the brain, in the sense in which the weight, or the harmoniousness, or the value of the brain are qualities. Experiences are not

qualities, but essentially the subjects of qualities. In short, they are substantial, and if they are not sufficiently self-subsistent to be themselves substances or things, they are at least elements in a substance, parts of it and not merely qualities of it.

This is not a verbal point. It is one of the principal issues in dispute. But the proof is not doubtful. \* That experiences are not qualities but the subjects of qualities may be demonstrated in a line or two. Because they are acts of reference, they are not universal but particular existences, and if qualities are not universal there is an end to any clear or important distinction between substance and quality, and the word quality is meaningless. Moreover, it is futile to argue that experiences are the acts of the brain. The brain does not refer to an object, and the acts of the brain are movements in space. The sense in which knowledge or feeling or will can be said to move is merely metaphorical. Introspection reveals a new world, and not merely new features in an old world. The new world may have arisen from the old, and the manner of its emergence may be obscure. But of the fact itself there is no reasonable doubt. The new world, in itself, affords a starting-point which is fixed and substantial.

Let us pass, then, to more specific problems of the self as knower and, first, to the problem of the *content* of cognitive experiences. We are accustomed to suppose that the mind of man is infinitely complex, rich with the most varied ideas, full, in short, of content. The analysis of this essay, on the contrary, seems to rob mind of these contents, or at least of cognitive content. An act of cognition seems to become a mere apprehending point, in itself colourless or, to use Mr. Moore's phrase, diaphanous. There are indeed differences in the 'quality'<sup>1</sup> of cognition. An act of assent, *e.g.*, differs from an act of

<sup>1</sup> In the technical sense explained.

doubting. But that, surely, is a very jejune estimate of mind's estate. The wealth of mind seems to consist in its ideas, and the wealth of any particular mind in the range of ideas in which it is at home. In conformity with our analysis, however, we must maintain that all such presentations, however subjective, are not, in the strict sense, parts of mind at all. Acts of cognition refer to these presentations, but do not contain them; and the specific contents of the acts, except for differences of 'quality,' seems to be a tenuous thing which defies description. The difficulty seems more pronounced in the case of cognition than in that of feeling or will. There seems more body in the latter when abstraction is made from the object to which they refer. Such abstraction is essential when the problem in dispute is that of the content of the self; and an act of apprehension, regarded in abstraction from its object, seems to have lost most of the marks of distinctive particularity.

This seems a serious difficulty. It is easy to maintain that the act of mind which refers to one object is different from an act of similar 'quality' which refers to another object. Does not the act of perceiving blue differ from that of perceiving green, even granting that no act is ever, in itself, either blue or green? Is it not evident that the act of perceiving a circle is, *quâ* act of perception, different from the act of perceiving a square, although neither act is in itself spatial? Perhaps it is so, but how can we prove it? Each act refers to a different object, but it is possible to specify the difference between them in one way only, and that way is to specify the objects. The awareness of blue differs from the awareness of green, because we are aware of blue in one case, and aware of green in the other. So it might appear that the acts, perhaps, do not differ *inter se*, except numerically, and that the only difference is in the objects.

Indeed, the seeming obviousness of the qualitative difference between acts referring to different objects may be due to confusion. Take the case of the square and the circle, for instance. We cannot perceive a square without making certain ocular adjustments, and these adjustments are different from those which are implied in the perception of a circle. When we perceive either of these we are aware, not merely of the square or the circle, but also, at the same time, of certain bodily movements which the analysis of space-perception has brought into great prominence. All this, however, is irrelevant to the mental acts themselves. The adjustments, from the point of view of cognition, are only presentations of which we are aware in the same sense as the square or the circle. They are not parts of the perceiving mind, and consequently the fact that they must always accompany the acts of perceiving the square or the circle does not prove anything concerning the intrinsic nature of the acts themselves.

To raise the question at all may seem a *reductio ad absurdum* of the whole position, and there are many who would say that the conception of the mind as an apprehending point is intrinsically absurd. In a way it is absurd, because it is the product of over-refinement of analysis. The mind is not merely cognitive, and even its cognitions, its knowledge, form a system. But, neglecting this, it still seems true that our analysis robs the mind of something peculiarly its own. The reply, however, is even more obvious. Can an act ever be identical with its object, can our thoughts of blue be blue, or our thoughts of the chimera non-existent? If they cannot, and it is plain they cannot, how can the characteristics of the object be said to belong to the mind? It is impossible to say that 'content' or 'meaning,' in the ordinary sense of the idealists, is part of mind. For meaning, if it is not an act, is what is meant,

and content, if it is not the reference to the object, is something contained in the total object of cognition at any time. Are sensations, perhaps, vehicles of knowledge, and contents in that sense? They are vehicles in the sense that the mind may pass through them to physical and other substances, but they are not, therefore, parts of mind, any more than the train which is a vehicle for conveying me to Dublin is a part of me or my body. No phraseology will alter facts, and it is unwise to use any for purposes of concealment. What we ought to do is to realise that some objects are mind-dependent in a way that others are not. Other men are not dependent on a finite mind, God is not and the stars in their courses are not. But the brightness of the stars and the colours of the human countenance may possibly be thus dependent, and, perhaps, the primary qualities as well as the secondary. The precise sense in which these are mind-dependent is a different matter. On some theories they are a sort of joint product produced by the interaction of mind and its environment, and so are existent entities which mind has helped to fashion. On other theories they are only fragments of the real, and are mind-dependent in the sense that the limitations of the subject account for the fact that just these fragments, and no others, appear at any given time. But on either theory no image, or *sensum*, or percept is part of mind, however much it may owe its existence, as a seemingly independent entity, to the observing mind. There is no robbery in the case, but only greater precision.

One argument on the question is especially relevant because it points the way to the new set of topics which confront us. Mental acts, it is said, must differ qualitatively if association, apperception, and similar processes are to be intelligible. It is clear that association is not of things as they are in themselves. It is a personal matter varying with

the experience of the subject who associates. Things are connected in various ways, but we associate only the connections we have noticed, and if the way in which we originally noticed them was erroneous, that error will continue in our associations. It would seem, then, that the explanation of the laws of association must be sought in mind and not in the objects themselves. But it is equally clear that we do not associate mental processes as such. We do not associate acts, but the objects of acts. Let us choose an example of association at random. I think of the fountain-pen before me, then of gold, then of chryselephantine statuary, then of Athens, then of Cleon, then of the Gracchi. I associate, therefore, not my mental acts, but certain things and persons, and each link in the chain of association is determined by some connection which I have previously noticed, or think I have noticed, in these objects. The nib of the pen is made of gold, Cleon and the Gracchi were democrats of different types, and so forth. It would seem, then, that the ground of the association must be found in the mental processes, each of which must specify some particular object; and, in that case, since every cognitive process must refer to an object, it is natural and inevitable that the association should refer to, should be *of*, objects. But unless each act, as an act, has a distinctive character in virtue of which it refers to a distinctive object, how could such association be possible? The acts are the only mental processes concerned, and if they did not differ as acts anything might associate anything. Similar arguments hold for apperception.

These are strong arguments, perhaps conclusive. The denial of them implies the formulation of some positive theory of association which will explain the facts at least equally well, and it is very hard even to suggest such a theory. I should like to suggest, however, though very diffidently, that there is at

least one other possible alternative. It may be that association is both of and through presentations, and that the mind only enters in so far as it has already contributed to the being of these presentations. On certain assumptions, at any rate, presentations are real, and they might very well behave according to their own laws.<sup>1</sup> So far as the hypothesis of psychical dispositions is rendered plausible by its connection with its physical correlates in the brain, that type of explanation would seem to refer to presentations at least as much as to psychical acts. By presentations, in the present connection, I mean sense data, images and the like, and I shall return to this obscure and difficult question later. For the present it is enough to say that each specific mental act has probably a specific difference according to the different object referred to. But if so, this difference can only be defined through the characteristics of the object.

There are many arguments which attempt to prove that the direct analysis of knowledge implies a soul substance in a special sense. Knowledge is thought to imply a soul which is something more than a plurality of cognitive acts, however closely these are connected together. Such arguments lead us into considerations which we have hitherto refrained from discussing, though they will occupy us much in the sequel. They are drawn, of course, from a great variety of sources, and are not restricted to the analysis of cognition. But sometimes it is held that

<sup>1</sup> If this theory is true it implies that presentations, as presentations, have an existence of their own, although mind may contribute to the making of them, and this view raises formidable difficulties. If presentations have an existence distinct both from mind and the physical object, then not only is the manner of their production unexplained, but the reality of the physical object becomes hypothetical. If, on the other hand, the physical object is only a descriptive name for a collection of presentations, somehow connected together, the problem of error seems to become insuperable. A *presentation* must be what it appears, and nothing else appears according to this theory. Even if this difficulty were overcome, others would remain; vide C. D. Broad, *Perception, Physics and Reality* (especially chap. III.).

the analysis of cognition shows directly and conclusively that there must be a knower over and above acts of knowledge. The form in which this argument is stated usually implies ulterior considerations which we must neglect for the moment, but the nerve of the argument need not be dependent on these implications of its form.

One of the clearest statements is Lotze's, and we may therefore examine it. The self, he says, cannot be simply the result of the confluence of a number of components destitute of any centre. 'Inner experience offers us the fact of a unity of consciousness. Here then is . . . the unassailable ground, on which the conviction of the independence of the soul can securely rest.'<sup>1</sup> And Lotze proceeds to develop this point. It is false to say that a psychology without presuppositions should be a psychology without a soul and should speak, to begin with, of sensations or ideas only. 'A mere sensation without a subject is nowhere to be met with as a fact.'<sup>2</sup> Movement presupposes matter, and similarly a sensation presupposes the subject which has it. It is true that reflection alone convinces us that every sensation expressly implies a conscious self. We often forget ourselves, so much are we absorbed in the content of our sensations, but that fact does not alter our verdict when we come to reflect. And there are other instances of cognition which dispel any lingering doubts which the analysis of sensation by itself might leave. 'Any comparison of two ideas which ends by our finding their contents like or unlike, presupposes the absolutely indivisible unity of that which compares them: it must be one and the same thing which first forms the idea of  $\alpha$ , then that of  $b$ , and which at the same time is conscious of the nature and extent of the difference between them.'

<sup>1</sup> *Metaphysic*, English translation, vol. II. p. 169.

<sup>2</sup> *Ibid*

Then again the various acts of comparing ideas and referring them to one another are themselves in turn reciprocally related; and this relation brings a new activity of comparison to consciousness. \* And so our whole inner world of thoughts is built up; not as a mere collection of manifold ideas existing with or after one another, but as a world in which these individual members are held together and arranged by the relating activity of this single pervading principle. This then is what we mean by the unity of consciousness; and it is this that we regard as the sufficient ground for assuming an indivisible soul.’<sup>1</sup>

This conclusion, he continues, is necessary. The unity of consciousness cannot be merely the combination of component processes. Even if we could thus speak of a centre of unity of an organism or machine (which is not the case), we must employ a different conception in the realm of the psychical. In this instance we have on our hands a totally new fact. We have a subject which brings together and compares its states. The investigator compares the states in the unity of his own consciousness. Even if this subject were, as Leibniz maintained, a central monad, it would still have a distinctness and an individuality as compared with the other monads. Accordingly we cannot dispense with the soul, and the best and clearest way of stating this result is to say that the soul is a simple and indivisible substance. Lotze, as we have seen, maintains that he uses this expression ‘in all innocence,’ i.e. neglecting metaphysical perversities. Substance is but ‘the general formal designation of every way of producing and experiencing effects.’<sup>2</sup> ‘The fact of the unity of consciousness is *eo ipso* at once the fact of the existence of a substance.’<sup>3</sup>

The main stress of the earlier part of the argument

<sup>1</sup> *Metaphysic*, English translation, vol. ii. pp. 170, 171.

<sup>2</sup> *Ibid.* p. 175.

<sup>3</sup> *Ibid.*

lies in its rejection of presentationism. The self must certainly be more than a collection of sensations or ideas if these words are used, as they should be used, to mean the material of cognition. There is the reference to the object as well as the object itself, and we have already insisted on this point so frequently and so emphatically that further recapitulation is useless. Indeed we have gone so far as to maintain that presentations, in themselves, are not parts of the self at all or, strictly speaking, states of it. They are for the self, not of it. They may be subjective, but that is quite a different matter. We are at one, therefore, with Lotze in his rejection of presentationism.

Again Lotze maintains that the substantiality of the self is identical with its unity and indivisibility. We may therefore, in the present instance, confine our attention to the unity and indivisibility and neglect the general problem of substance. His argument, then, is (1) that the indivisible unity of consciousness is seen most explicitly in a single act of comparison, (2) that there is a unity of these acts of comparison themselves, (3) that the essence of the knowing self is an activity which holds together the objects or ideas compared.

It is true that, in an act of comparison, the objects compared must be held together, and since we can compare the most diverse things, the main reason for the selection of the given objects must lie in the self, not the objects. And again, in any act of comparison there is a clear unity of knowledge as well as in the process of comparison. The objects are held together, and a connection is found between them. When, in a judgment, we assert that there is a connection between two or more terms of a proposition, it is implied that the unity of terms in relation is something ultimate. The proposition does contain terms, and it does contain a relation, but it cannot

be reduced to terms and relation. It is the unity of these, and that is the simplest fact of the case. And similarly, the act of assertion in such an instance cannot be reduced to the simple apprehension of the meaning of the terms and the relation involved. It is an assertion of their unity and implies a corresponding unity in the act of the self. There is therefore a very distinctive unity in the cognitive self when it frames a judgment of comparison. Such a unity, again, may be called indivisible for the very plain and sufficient reason that *every* unity is indivisible. The constituents of a unity may be discovered by analysis, but analysis is not division. Division destroys a unity. Analysis makes it intelligible, and is subject throughout to the control of the unity which is analysed.

We may say, then, that the cognitive self, at any given moment, is an indivisible unity; but it does not follow that Lotze's reasons for his conclusion are as sound as the conclusion itself. The distinction of cognition from its object is not proved by the unity of cognition. On the contrary, there is an equal and a corresponding unity in the object. When, as a result of comparison, we discover an objective connection, there is, as we have shown, a unity in the object. The object (let us say, the proposition) is a unity of terms in relation. This unity is not made by the act of comparison. The act of comparison may arrange the material which we wish to investigate, but this arrangement does not make the unity. The self is distinct from its object not because it is a unity, but because the object of knowledge is never the same as the knowledge itself. And again, the unity or the indivisibility of the self does not demand that the self contains no multiplicity. There is no unity worth the name which does not contain multiplicity. It is not very easy to see precisely what Lotze's contention is, but

there are indications that he meant something like this: 'In an act of comparison we connect certain *disiecta membra* together, and, as a result, obtain a unity. This unity cannot be accounted for by the *disiecta membra* themselves. We must therefore suppose that the self is an indivisible unity, and that this single active unity produces the result of comparison and presents us with a whole.' If that is his theory it ought to be rejected. In the first place, knowledge is not an activity of arrangement at all. In the second place, it need not be a single principle in the sense of a principle bereft of multiplicity. So long as it is a unity the conditions of the argument would be satisfied. In the third place, there is unity in the object as clearly and unmistakably as in the self. Consider the consequences if there were not. If the unity of the objects of knowledge depended upon the activity of comparison it would cease when that comparison ceased. The world would be connected by the accident of individual thoughts. Lotze, so far as one can see, is referring to an individual self, and so no other deduction is possible on his theory. If he were speaking of God's thoughts (or M's thoughts, as Lotze puts it), the problem might not appear so hopeless. The real world is that set of objects which are held together in unity by the continuous knowledge of the divine self. But God's presentations are not our presentations, nor is His knowledge ours. Where, then, does *our* world come in? Lotze has proved that the self cannot be the unity of the objects of experience. Has he proved that it must be more than experiences?

Moreover, when Lotze says that 'the various acts of comparing ideas and referring them to one another are themselves, in turn, reciprocally related,' he seems to introduce a fresh and a serious difficulty. If the unity of ideas compared implies a self distinct from these ideas, then, surely, the comparison of the unities

thus obtained will require a new and distinctive unity of self to compare them. In terms of Lotze's definition it will require a new, simple, and indivisible substance, and we should therefore require a plurality and a hierarchy of selves until we reached an arch-self which compared all ideas and all the lesser unities implied in the construction of particular judgments. Lotze would reply, of course, that it is one and the same unity which compares particular objects and constructs the whole world, but the statement quoted implies that the acts of comparison can themselves be compared, and if every comparison implies a unity over and above that of the objects compared (and that is his argument), then he has no right to deny the manifest consequence. He cannot say that we find on reflection that the unity of the comparison of objects and the unity of the comparison of these acts of comparison is one and the same; for that, in its turn, implies that a unity can be discovered, not made, through an act of comparison, and in that case the unity *found* in objects compared would not, by itself, presuppose a self; all of which goes to prove that Lotze's conclusion is better than his arguments for it. He has proved that psychical processes exist, are connected and must be distinguished from their objects. He has proved nothing more.

- It may be maintained, however, that the existence of self-consciousness proves that the knower is more than his cognitive experiences. Particular acts of consciousness might be seen, by an external observer, to form a unity. He might see that they were not a mere bundle, but must cohere as an individual psychic centre. But then this centre has the peculiarity of being aware of its own unity. It is self-conscious, and as consciousness must be distinguished from self-consciousness, so the self must be distinguished from its consciousness, whether that consciousness is a unity or not.

Now the relation of consciousness to self-consciousness is something of a problem, because self-consciousness may mean so much. Does it mean, as the scholastics declared, that the self, unlike everything else, has the peculiar property of being totally reflected upon itself? Is it identical with Leibnizian apperception? That, as is well known, is the distinguishing characteristic of the highest grade of monads. There are monads which are bare monads. They have a minimum of perception and appetition, but only a minimum. Next to them come souls which possess, in addition to perception and appetition, the faculties of attention and memory. But above this is the realm of spirit whose *differentia* is apperception or self-consciousness. That is the index of rationality. 'These souls have the power to perform acts of reflection, and to consider what is called the ego, substance, soul, spirit, in a word, immaterial things and truths.'<sup>1</sup> Such spirits can know God and the *eternae veritates*. Is it, again, that which is vindicated in Kant's deduction of the categories, the '*ich denke*' which must be able to accompany all my representations? Or is it, as with Hegel and some Hegelians, Absolute Spirit, that synthesis of idea and nature which Hegel, with splendid audacity, attains through the infinite labour of the Notion? These views, I suppose, have much in common, but they also differ. And if we had thoroughly discussed them we should also have discussed the whole range of philosophy.

For clearness' sake I propose to distinguish self-consciousness from self-cognition, and to discuss the latter. By self-cognition I mean simply the knowledge which we can obtain of ourselves by introspection, together with the deductions that can be drawn from this knowledge. Self-cognition, on any theory, is the basis, or at least the criterion, of self-consciousness. When we are capable of performing this reflection,

<sup>1</sup> Gerhardt, *Die philosophischen Schriften von G. W. Leibniz*, vi. 600.

this self-cognition, when we not only know, but know that we know, when we can notice that our experiences are parts of ourselves, when we can know ourselves as ourselves and as distinguished from all else, then we have attained a stage of rational, clear, coherent thinking which is symptomatic of a high, if not the highest, level of mind. This level, with its implications, is called self-consciousness, and since much of our consciousness at this level is not concerned with itself at all, but rather with the *eternae veritates*, it follows that self-consciousness is much wider than self-cognition. It is on the possibility of self-cognition, however, that the argument which we are now discussing depends. Does the fact of self-cognition show that the self is more than its experiences, cognitive or other?

Self-cognition, then, is an act of knowledge referring to the self. Such an act cannot be part of the series to which it refers, and therefore (it may seem) we have grounds for distinguishing the 'pure' from the 'empirical' ego, the ego which is essentially subject from the ego which may be object. We have seen that acts of cognition, and other psychical processes, are not primarily objects of consciousness, but may become so. They are such objects when there is self-cognition. An act, however, can never refer directly to itself. Does it not seem, therefore, that there must be an arch-ego to make self-cognition possible? The ultimate judge cannot be its own object. †

I do not think the consequence follows. In any act of self-cognition the object is a series of experiences, and that series must form a unity, if it is a self. As we shall see, there is a self, not merely because there are experiences, but principally because these form a distinctive kind of unity. In self-cognition, of course, it is *my* self which I cognise, and so there seems to be the contradiction that the

act of self-cognition and its objects must be part of the same unity which is cognised.

But is there really any contradiction? It never happens that the whole self is present to us in self-cognition. That would be impossible because the self of which we are aware to-day also existed yesterday, and we have forgotten much of yesterday. It will also, this same self, exist to-morrow in all probability, and we do not know what the morrow will bring forth. There must, therefore, always be inference as well as direct revelation. The question is not whether we can ever envisage the whole series of our lives, but whether what we do envisage is part of ourselves, and how we can extend this by inference. Now there are certain criteria of self-hood which it will be the purpose of the rest of this essay to discover, and our principle is that any experience which has these characteristics is part of the individual unity which we call ourselves.

If we have formed the habit of introspection, it will follow that when we take stock of our lives or, in other words, perform an act of self-cognition, we find that previous acts of self-cognition are parts of the self. They are as truly parts of the self which is past as any other acts which we performed. They have the marks of self-hood, and are commingled in the unity of experiences which is the only self we can discover when we reflect. It follows from this, not only that an act of self-cognition need not be on a different level from other psychical acts, but that we have no evidence that it could be on any other level. If we are aware of ourselves as a unity we must really be a unity; if we are aware of a previous act of self-cognition as part of this unity, it must really be such a part and not anything else. And since we can infer that the unity of the past may be continued to the future, we can make the same inference to acts of self-cognition

which cannot be their own objects at the time they are made.

One objection remains. It may be said that to know, and to know that you know (which is an implication of self-cognition), must be one and the same, since, if they were not, there would be an infinite regress. And it is true that there would be an endless regress for any one who cared to continue the process of introspection of previous introspections endlessly. But that would be only a tedious superfluity, and there is no implication of a *vicious* infinite. To know is the *præ* of knowing that you know. Cognition does not logically *depend* upon self-cognition, nor one act of self-cognition upon the next.

In conclusion it is necessary to mention a slightly different, though cognate, type of argument which Mr. Bertrand Russell brings forward: 'When I am acquainted with "my seeing the sun," it seems plain that I am acquainted with two different things in relation to each other. On the one hand there is the sense-datum which represents the sun to me, on the other hand there is that which sees this sense-datum. All acquaintance . . . seems obviously a relation between the person acquainted and the object with which the person is acquainted. . . . Thus, when I am acquainted with my seeing the sun, the whole fact with which I am acquainted is "Self-acquainted-with-sense-datum."

'Further, we know the truth "I am acquainted with this sense-datum." It is hard to see how we could know this truth, or even understand what is meant by it, unless we were acquainted with something which we call "I." It does not seem necessary to suppose that we are acquainted with a more or less permanent person, the same to-day as yesterday, but it does seem as though we must be acquainted with that thing, whatever its nature, which sees the sun and has acquaintance with sense-data. Thus, in some

sense it would seem we must be acquainted with our Selves as opposed to our particular experiences.<sup>1</sup>

This argument expresses in a chastened and modified form what other writers are apt to express much more sweepingly. Mr. Russell does not claim that he is directly aware, by introspection, of a self which is other than, and irreducible to, particular experiences. What he says is that it is possible to prove indirectly, from the fact of introspection (or self-cognition), that knowledge involves a self which is not the process of knowledge, and he does not pretend to know what this self is, or how long it must continue. Such ignorance is strange. Introspection, although fallible and difficult, is frequent enough, and if it is possible to demonstrate that introspection always implies a self in this sense, then it is very surprising that, when we have found where the self must be, we are still unable, by precise inspection, to tell what it is.

The argument, I think, proceeds on a false assumption. It seems to imply that the experience of being acquainted is only a relation, an analysis which is false if and so far as acquaintance is a cognitive act. There must be a relation between the act and the object, but this relation is not the act itself. When the self is acquainted with a sense-datum, its acquaintance is not a relation between the self, on the one hand, and the sense-datum on the other. The primary relation, at all events, subsists between the act of acquaintance and the sense-datum, and this relation is simply that the acquaintance is *of* the sense-datum. The fact that such a relation holds, does not imply that any *term* other than the acquaintance exists. Accordingly the argument is irrelevant if it is meant to prove that the self is more than its experiences, and perhaps Mr. Russell did not try to prove that. But if the self is the

<sup>1</sup> *The Problems of Philosophy*, pp. 79-80.

unity of these experiences, then we do know what it is, and need not speak with Mr. Russell's reserve. It is 'more or less permanent,' because the unity of experiences persists through time.

That, however, is a problem for the sequel; and so we may pass to the new set of questions implied. As we have seen, time and again, the unity and continuity of the self, and the conception of the soul which makes this unity intelligible, are the most important problems at issue. Indeed the discussion, up to the present, has been little more than an introduction to these fundamental questions.

## CHAPTER IX

### THE UNITY AND CONTINUITY OF THE SELF

UNITY and continuity are the most distinctive features of the selves which we know. Detached experiences, if they exist, are not a self. To be parts of a self they must conspire together with other experiences to form an individual, continuous unity. And our discussion may seem seriously defective, because it has delayed so long before coming to this central problem. As Bergson might say,<sup>1</sup> the 'pénétration mutuelle' of ideas is the essence of the self. The multiplicity contained in the self, he would continue, is something *sui generis*; indeed, the self can only be represented, not thought, as a whole of parts. The distinction into parts is superficial, a sort of picture thinking which borrows a misleading plausibility from the associations of space and mechanics. And we may agree that the unity of the self is specific and distinctive. It is a more controlling and pervasive unity than any other. To describe the self as a unity is to say too little, unless we specify the particular kind and degree of unity which we mean. We might even say that the unity of the self preponderates over its multiplicity, were it not that such a statement would inevitably mislead. Unity and multiplicity, whole and parts, are always correlative. A part is meaningless unless the kind of whole of which it is a part is specified.

<sup>1</sup> See, e.g., *Les Données immédiates de la Conscience*, pp 100 ff.

Accordingly the method of exposition adopted in the previous chapters is defective only if it is misinterpreted. Psychological experiences *are* parts of the self, but that statement has no meaning unless it is understood to imply that they are parts of the kind of whole which the self is, and of no other whole.

On this assumption, and on this assumption only, it is legitimate and expedient to begin, as we have done, with the parts of the self (or, rather, with the parts of the empirical self). The chief danger of such a course of procedure is that it may represent these parts as simpler and more self-sufficient than they really are. We have spoken, for instance, of acts of cognition, acts of feeling, acts of endeavour, and have illustrated them by the simplest possible examples. But in reality they are parts of a very complex process and, in most cases at all events, they bear the traces of this complexity in their very being. An act of perception, for instance, seems a very simple matter. We perceive a tree, or a blackbird, or a ruin. Any one can do it. Where is the problem? But if we consider the very complicated meaning of these relatively simple instances, if we consider the multitude of subtle signs implied in such very obvious acts of recognition, we can easily see that these acts are, in reality, permeated with complications and reveal the stigmata of long development. And what holds of perception will also hold of any other psychological process.

The same result follows if we remember the point at which our analysis began. We began not so much with isolated acts as with the content of the self at any given time. We tried to discover what is revealed in a cross-section of conscious life, and we found that this cross-section contained a unity of cognition, feeling and endeavour. Thereafter we tried to examine the nature of these processes more carefully. But this mode of procedure cannot

possibly be final because the unit from which it starts, the cross-section it describes, is quite arbitrary and chosen merely for purposes of convenience. The cross-section is only a mathematical line. It has no breadth; and if we so interpreted it that it had breadth, if we maintained, for instance, that our unit was the 'specious present,' the procedure would still be arbitrary. It may be true that the passage of consciousness is something like the movement of a bird. It is an alternation of flights and perches.<sup>1</sup> The perches seem to focus the results of the previous process, and to hold them together in a single unit of time which occupies a sensible duration, and is called the specious present. But, even in this instance, the flights and the perches are continuous. The flights are not gaps in consciousness, nor are they mere means to the perches. To continue a metaphor that is already overstrained, the momentum of the flights quivers through the perches. To drop metaphor, no section, or set of sections, of psychical life constitutes an individual self.

\* At the same time it is not altogether useless to analyse these fragmentary glimpses of the self. The general type of unity which is found in any moment of its existence pervades its whole life. The life of the self is a unity of cognition, feeling and endeavour. These elements are continuously present; they must exist whenever a self exists; they develop together, and decline together. And so in our discussion of the unity and continuity of the self or, in other words, of personal identity as that appears in concrete experience, we shall consider cognitive unity, conative unity and affective unity respectively, remembering the while that these distinguishable strands of unity are themselves connected.

Some preliminary explanation, however, is essential. • While it is true that the three principal modes of

<sup>1</sup> James, *Principles of Psychology*, Vol. I. p. 243.

consciousness develop together, and that they imply an interconnected development, it is false that the development of the three is parallel in every respect. There must inevitably be some correspondence between them, but just as, at any given moment, one of these elements may preponderate over the other two, so it may show a relatively permanent predominance in a given person. Some men and women, as we know, are prevailingly emotional. The passionate, the artistic, the poets and the mystics agree in this, widely as their emotions differ in kind and in value. Others, again, are prevailingly reflective and intellectual. They are the classics, not the romantics. They keep their emotions in check. They look before they leap, if, indeed, they leap at all. And, finally, there is the energetic type which is determined to do something, whether that something is worth the doing or not. Of such are the Marthas who wipe invisible specks from immaculate silver.

In such instances it usually happens that the predominant 'faculty,' to employ a useful if maligned term, sweeps the others in its train. The poet is not a mere mass of feeling, or the aesthete all compact of sentiment. Both of them think, and both strive. Their thoughts, however, are, for the most part, concerned with their feelings, and their endeavours are towards those feelings. We do not expect Wordsworth to be a formal logician, or Turner a speculative genius. And so of the rest. The whole mind of Martha has a different trend from the whole mind of Mary. But although we should frequently be right in classifying our acquaintances according to some distinctive type, we should even more frequently be wrong. It seems absurd to think of Milton or Spinoza smoking a pipe, and yet both were accustomed to do so. It is false to assume that these great men, in their normal lives, felt nothing but the rarefied pleasures of the intellect. Some things may conform

to type, but selves have a provoking habit of diverging from it. It is not only in matters of religion that Davie Deans is constrained to be a Deanite. Keen speculative powers are sometimes conjoined with delicacy of feeling, but sometimes they accompany, if not mere sensuality, at least a surprising lack of sensitivity. There is no measure wherewith to mete these things. Human beings diverge in this respect as much as in others. The most diverse attainments sometimes accompany one another and sometimes do not. Philosophers and novelists and mathematicians are not usually good men of business. But the India Office had no reason to be dissatisfied with Mill or Peacock, or the Mint with Sir Isaac Newton.

The same kind of consideration may supply us with another salutary warning. 'It is true that the unity and continuity of the self is more intimate than any other sort of unity or continuity which we can discover by experience.' None the less, that intimacy of union can be so exaggerated as to contain more error than truth. The human self, we say, can look before and after, can reduce its information to system, can plan large enterprises and carry them through. That is true. There are many who can do these things, but there are more who either do not or cannot. We read of dual or multiple personalities, not only in fiction, and we are surprised; but we ought not to be so much surprised as we are. The lives of many of us show a wanton disregard of unity. Traits of character appear which seem totally out of keeping with the general trend of the life, and often it seems impossible to say that a particular life has a general trend at all. To maintain that human personality is a complete and balanced unity is about as absurd as to argue that every member of the human species is a sort of compound of Sir Isaac Newton and Sir Henry Lawrence.

Remembering these provisos we may now proceed with our task. Let us consider, first of all, the cognitive

unity of the self. The various cognitive experiences of a self have a certain unity and continuity. The evidence for that unity is to be found in the comparison of the results of introspection, and of what is directly remembered. And there are general arguments which go to prove that any experience, to be an experience at all, must imply a considerable measure of unity. The most famous and the strongest argument, on this head, is Kant's deduction of the synthetic unity of apperception. We may, therefore, begin by considering it, more particularly in the form in which it appears in the first edition of the *Critique of Pure Reason*.

The aim of this famous deduction is to prove that knowledge of any sort is impossible unless there is unity both on the side of the object and on that of the subject. The deduction in the first edition, unlike that in the second, begins its analysis from the subjective point of view. Our ideas, Kant maintains, are phenomena, and if he does not mean that they are modifications of mind, he at least implies that they pertain to the internal sense. The form of the internal sense is time, but to say that ideas are in time is not a sufficient account of the matter. We must be conscious of the temporal relations of these ideas in order to represent them as a unity, and this consciousness of relation in time cannot be given by its mere occupation of time. An idea, as an occurrence in time, lives for a moment and then vanishes. To be aware of its connection with preceding and succeeding ideas in time, i.e. to be aware of its temporal relations, demands that we should be aware of it, and its predecessors, and its successors all together. There must, in other words, be a synthesis which runs through this manifold of ideas and grasps them together in a unity. This synthesis is called the synthesis of apprehension.

That, however, is not enough. Our ideas are connected together by certain laws of association in such

wise that when two ideas have frequently occurred together, the occurrence of the one inevitably brings about the recurrence of the other. But it is impossible to explain this fact in terms of association only, for the very good reason that the subjective connection which is association presupposes an objective connection as the condition of its possibility. 'Supposing vermilion were at one time red, at another black—at one time heavy, at another light; were a man changed first into one, then into another animal—were our fields covered on the longest day, at one time with corn, at another with ice and snow—then my empirical faculty of imagination would never have had even the opportunity of thinking of the heavy vermilion when red colour was presented to it.'<sup>1</sup> In other words, we cannot acquire the habit of passing from one idea to a connected idea until we have had frequent experience of the actual connection. The argument really is directed towards distinguishing the subjective from the objective order in a series of ideas of the internal sense. Kant, however, uses it, for the time being, as illustrative of another point. There must be a synthesis of reproduction as well as a synthesis of apprehension. If, *e.g.*, we are aware of a temporal span of any duration we must hold it together in its totality, and consequently must be able to reproduce those portions of the span which do not synchronise with the immediate present of apprehension.

Kant argues, in the third place, that knowledge, to be possible, requires a third type of synthesis, which he calls the synthesis of recognition. To apprehend the meaning of any process, let us say that of counting, and to be sure of the validity of our results, we must not only reproduce the earlier ideas implied in our idea of the result, but we must recognise the identity of that which is reproduced. We must deal throughout

<sup>1</sup> This translation is taken from Mahaffy and Bernard's edition of Kant's *Prolegomena*, Appendix I. pp. 159-60.

with the same units, and recognise that we are doing so. The simple process, therefore, of the formation of any concept involves a unity of consciousness which is very distinctive and very complicated. Kant admits that this consciousness 'may often be weak, so that we perceive it only in the result, and not in the act.'<sup>1</sup> But we must possess it, whether it be weak or strong, clear or obscure.

I do not mean that this account must be accepted *au pied de la lettre*. There is considerable doubt, for instance, concerning the necessity for actual reproduction. When we compare, the terms compared must both be present to the mind, but they need not both exist together, because the mind may refer to a past state of existence. This direct reference to a past object is memory or recollection, in the strict sense, and it need not imply any reproduction of the past object at the moment at which that object is remembered. Even if there were reproduction we should require to compare the reproduction with the original. A reproduced object is a new object, and must be compared with the past object *itself*, in order to know that it is a reproduction. Therefore we must be acquainted with the past event itself in memory, and what Kant has really proved is the necessity for retentiveness,<sup>2</sup> and not for literal reproduction, whether that occurs in fact or not. Similarly, the argument is independent of many particular interpretations of the word phenomenon. It may hold whether or not the 'internal sense' is construed in Kantian fashion or phenomena explained as modifications of mind. But, in essentials, Kant's argument stands.

The nerve of the argument, especially of the passage quoted *in extenso*, is the same as the later

<sup>1</sup> This translation is taken from Mahaffy and Bernard's edition of Kant's *Prolegomena*, Appendix. I. p. 162.

<sup>2</sup> In the sense which implies the power of recollection in any form, and the leaving of traces in mind.

deduction of the principle of causality. All our ideas, *i.e.* all the phenomena of which we are aware at any time, occur in time, but we must distinguish the subjective from the objective temporal order of these ideas. We may think of what we did on Tuesday before we think of what we did on Monday. In that case the idea of Tuesday, subjectively, precedes the idea of Monday. But all our thinking becomes meaningless unless we know that, in fact, Monday preceded Tuesday. The whole argument, be it noted, takes place within the realm of phenomena or, in our phrase, the 'material' of our cognition, and the strength of the argument is that it is independent of any ulterior metaphysical theories of the nature of things as they are in themselves. According to Kant, phenomena themselves supply the characteristics of universality and necessity, and this is the ground for the fundamental distinction between the subjective and the objective orders. Necessity and universality are marks that ideas cannot occur at random, and so we must conclude that there is a somewhat which prevents them from doing so. Ideas, he maintains, are phenomena; and therefore we cannot specify the noumenal ground of objectivity through them. But the unity and order of ideas, their necessary connection especially under the forms of space and time, is an order which is objective because it must be conditioned by something other than subjective ideas. And the further point is that the knowledge of the subjective order itself, in any form or degree, presupposes this knowledge of objectivity. There could not be subjective association unless there is also the possibility of the knowledge of objective relations.

Let us take any concrete illustration. The perception of the tree or the blackbird, which I have mentioned, is a very complex affair. We recognise that we are thinking of a tree or a blackbird, and know them distinctly enough to call them so. There

may be, and are, disputes as to what in this complex is given to us and what is matter of inference, but these difficulties are irrelevant in the present connection. We interpret what we see as a thing, and a particular kind of thing, to wit a blackbird or a tree; we recognise it as part of a spatial context, and occupying that context at the present time and not at any other time. All this implies the categories or principles of spatial and temporal order, of thinghood, and perhaps of causality, since we think of what we perceive as bound together by conditions which do not depend on us. Our object of perception, therefore, is and must be complex, and must involve general principles of the connection of existence. What is more, such complexity and order is the least that can be demanded. Our random thoughts, it is true, seem exceptions to this regular order, and we distinguish them on this ground. We can all distinguish dreams from waking. But the dream world is only possible because the waking world is possible. It is a shadow of the waking world, copies it in its characteristic features, is secondary and derivative. The essence of Kant's argument is to show this clearly, and, in particular, to prove that fleeting and subjective experiences can only be said to be known at all, or to be in any way present to mind, if mind can also know and distinguish this objective order. Anything that is known must be capable of being recognised for what it is, a recognition which implies acquaintance with these general principles of order. And that account holds good of *any* object of cognition.

Since, then, the object of cognition must be both complex and connected, it follows that the cognition which refers to this object is also complex and connected or, in other words, forms a unity. Acts of cognition are experiences referring to an object, and they are distinguished and described by means of

the objects to which they refer. — There must, therefore, be a 'one-one' correspondence between act and object, however difficult it may be to specify the content or the unity of the act in contradistinction to those of the object. The mind grows as the objects revealed to it grow. It is not more of a unity than what it knows, nor is it less of a unity. It does not overlap its object but is coextensive with that object. Nothing else, indeed, is possible, or has any meaning. And because, as Kant has proved, retentiveness is necessary to any knowledge, it follows that the unity of mind at any time is stamped with the message of the past. This fact is also the fact of its continuity through time, and a further implication of this unity and continuity is that any experience must also have a reference to the future. We live with our heads up stream.

This argument does not imply, in any way, that we cannot mean and intend particular things as such. We can and do intend them. But they, in their singularity, are not the total object of cognition at any time. We may, and do, select some part of the total object of cognition for special consideration, and most of our statements refer to it alone. But we know throughout that we are selecting, and this implies a knowledge of more than that which is selected. And again, it is not implied that the validity of knowledge somehow depends upon the whole system of knowledge. There is system, no doubt, but it is possible to know, and to know finally, particular connections within that system without any explicit knowledge of the rest of the system. A certain school of logicians and philosophers maintain that the ultimate subject of any proposition is reality as a whole. That is a theory, perhaps, which is susceptible of many interpretations, but if it means either that the knowledge of any particular truth logically implies the knowledge of the whole

truth, or that we try to know everything when we refer to anything, then it is false. When we judge that Caesar crossed the Rubicon we do not intend to refer to any man except Caesar or any river except the Rubicon. A great deal of history went to the making of that event, and it was rich in consequences. But we refer to none of these when we make the judgment, still less to anything else. It is worth while to devote some attention to this point in order to make it intelligible, and to show its consistency with our previous arguments, and for that purpose it is well to consider objections. A clear statement of the opposite case may be found in one of the chapters of Mr. Joachim's essay on *The Nature of Truth*, and we may therefore examine what he says.

The part of Mr. Joachim's argument which is especially relevant is that which defends the coherence theory of truth. Mr. Joachim urges that truth and falsity belong only to judgment, and that if we think of judgment as we ought to think of it, *i.e.* as a piece of concrete thinking, we shall see that its significance depends on its coherence. 'A judgment, as the inseparable unity of thinking and the object thought, is a piece of concrete thinking. The precise nature of its affirmation, its precise meaning, is largely determined by the conditions under which it is made. The judgment occurs in a particular context, it issues from a special background, it concentrates in itself various kinds and degrees of knowledge. Its meaning is coloured by all these determining factors, which together (and with others) constitute the medium of any piece of concrete thinking. . . . Every judgment, as a piece of concrete thinking, is informed, conditioned, and to some extent constituted by the *apperceptive character* of the mind which makes it, just as what the histologist sees under the microscope is conditioned by the scientific knowledge which has trained his "eye" and "informs" his vision. . . . To

the boy, who is learning the multiplication table,  $3^2=9$  possesses probably a *minimum* of meaning. It is simply one item of the many which he is obliged to commit to memory. . . . But to the arithmetician  $3^2=9$  is perhaps a shorthand symbol for the whole science of arithmetic as known at the time. As a piece of *his* concrete thinking, it may signify all that could be read into it and expressed by the best arithmetical knowledge hitherto attained.<sup>1</sup>

Mr. Joachim goes on to say that any body of knowledge, any science for instance, tacitly makes the same assumption. 'The scientific mind' probably does not exist by itself. It is a general expression for the thoughts of men of science so far as they are thinking about science and not about their own personal affairs. 'The meaning of any judgment of science is vitally dependent upon the system of knowledge which forms its context, and which is the "apperceptive character" of "the scientific mind" at that stage of its development. And this apperceptive character, as the "scientific mind" passes through the various stages of its development, undergoes a modification which is far more akin to the organic growth of a living thing than to increase by aggregation or to change by elimination and addition of constituent elements. . . . Would it be maintained that the discovery of the differential calculus left the contents of the "scientific mind" unaltered, and merely added fresh elements to the old stock? Has not the entire character of the mathematical mind been changed by the discovery, so that every judgment which it makes is invested with a new significance?'<sup>2</sup> These arguments seem very convincing, and suggest that there can be no truth short of the whole truth. The problem is how their cogency may be admitted without affecting the validity of our earlier contentions.

<sup>1</sup> *The Nature of Truth*, pp. 92-93.

There seems to be almost an antinomy. On the one hand any great scientific theory, such as the law of evolution, seems to give both the principles and the observations of science a new and a richer meaning and, indeed, to make them new. Where is the necessity for prolonged scientific training if it were not so? The embryo scientist must acquire an apperceptive system like that of his teachers before he can either appreciate the old discoveries or make new ones. On the other hand the stability of observed facts is a presupposition of any advance. The superiority of a new theory to an old consists in the fact that a greater number of recorded observations become intelligible upon the later theory than upon the earlier. Both theories set out to explain the same set of facts. If the facts changed, the new theory would not be the better explanation of the old subject matter. And there is another point. Much of the advance of science consists in singling out some particular element and holding fast to it. It distinguishes the *relevant* particulars more exactly than was previously done. The earliest experimenters carefully noted the position of the planets, at the time of their experiments, and took steps to exorcise the fiends. They were right on the basis of their knowledge. The planets might make a difference, and so might the fiends unless the experimenter made them 'bow to the force of his pentagon.' Nowadays we guard against other sources of error. The chief business of experiment is to learn how to neglect the greater part of the system of nature, and to hold fast the particulars in its despite. How can this antinomy be solved?

Let us begin by considering the schoolboy and his master, a particularly ignorant schoolboy, of course, and a particularly competent master. The schoolboy and his master both judge that  $3^2 = 9$  but, according to Mr. Joachim, the schoolboy's meaning in

making this judgment is quite different from his master's. The schoolboy means almost nothing, the master means the whole science of arithmetic. The question is whether this is a fair statement of the case, and that could only be settled if we knew precisely what each of them really meant. Let us suppose, for instance, that the schoolboy's knowledge is only the knowledge of a rule for manipulating mathematical symbols. The master's knowledge must include this knowledge, and the two, therefore, will be in partial agreement. The master may be more familiar with these rules than the boy, and more expert in calculating according to them, but this is a difference of degree, not of kind, and in so far as the particular act of reckoning is concerned, *i.e.* the act which declares that  $3^2 = 9$  and not  $9\frac{1}{2}$  or  $8\frac{3}{4}$ , the two are in absolute agreement, and mean precisely the same thing. Where, then, is the difference? The master knows that these rules of reckoning are instances of certain general principles. The schoolboy is not capable of appreciating these principles; it is enough for him if by following the rules he may qualify himself for the position of a book-keeper. The master may even know that the rules are only applications of the principles of symbolic logic, although the chances are that he neglects this consideration entirely when he corrects exercises or balances his own accounts. He prefers to keep his general apperceptive system in the background. In a sense, then, he may be said to mean (sometimes) something different from the boy. But in what sense precisely?

The difference is that the master knows what the boy knows, and also knows more. The symbols, for him, refer to a wider and more complex object, but this object includes the object which is also known by the boy. Mr. Joachim argues that this position is untenable on the ground that it amounts to saying

that the system of truth is only an aggregate of particular truths; but that interpretation is surely unnecessary. If I tell Horatio that there are more things in heaven and earth than any philosopher has dreamed, I surely cannot be taken to mean that the unimagined things have only a numerical relation to the others. The simple statement that there is a higher percentage of proof spirit in sherry than in beer does not deny that both may have causal effects on an organism, or prove that either of them is a mere aggregate. Everything is related to everything else, and the discovery of a new context means the discovery of new relations between a given thing and other things. The whole question is whether relations necessarily make a difference to the intrinsic character of the terms related, and it is not difficult to prove that they need not. There must be a relation between the act of knowledge and its object, and, therefore, if relations necessarily make a difference to their terms, it follows that we can never know any object as it is in itself, *i.e.* truly.<sup>1</sup> It is one thing, therefore, to maintain that when we think of anything, however simple, we must think of it within a context, and that the development of knowledge consists principally in discovering a broader, and yet a broader, context. It is another thing, and it is false, to maintain that the increase of knowledge necessarily affects the validity of any particular established truth.

These considerations, I think, are sufficient to prove the necessity for the cognitive unity and continuity of mind, and to defend this unity against misinterpretation. It is true that knowledge can never spring a total surprise, since it must blend with

<sup>1</sup> This, of course, is very controversial, but the answer is not doubtful if any truth can be quite true, and that is the claim of all truth, strictly understood. It is otherwise if a distinction is drawn between 'correctness' and 'truth,' and the conclusions of the intellect said to be so 'correct' as to be intellectually incorrigible. But that is the refuge of despair.

previous knowledge. It is true that almost every fact of which an educated mind is aware is either a clue to discovery or an instance of principle. Again, it is true that limitation of knowledge may breed error. The whole question at issue is whether it must invariably do so, and we have argued that it need not. Finally, it is important to guard against exaggerating the unity and continuity of the normal self as seen in experiences of cognition.

In the first place we must not suppose that all our cognitions are true. Error dwells with all of us, and error does not necessarily disrupt the self, except in a metaphorical sense. There are many minds which are content to lie in error, and even to construct a limited but tolerably consistent scheme of things upon a basis which is partially erroneous. The 'felt contradiction' which is the root of the Hegelian dialectic is frequently not felt at all. The highly developed mind feels it most. Other minds feel it seldom, if at all. The more we know, the more do obstinate questionings arise, and the more detailed and specific these questionings become. In the second place, while the unity of the self is very complete and striking in some respects, it is exceedingly incomplete in others. If we consider some complicated train of intellectual processes, let us say the estimation of evidence in a trial, then the unity of that process is very clear. There is a perpetual sifting of what is relevant, a perpetual purging of the irrelevant. Many alternative hypotheses must be conjointly entertained and due value assigned to each. At each step in the process it is necessary to keep the results of previous investigation in mind. Facts which, in most cases, would be trivial and unworthy of notice may, in this case, be fraught with deep meaning. But it is idle to suppose that the unity of the self (or of its object as known) is always, or usually, of this peculiarly close description. Such

a unity cannot be long sustained, and is probably never found in the total object of cognition at any moment, still less for a prolonged period. We are seldom, if ever, completely absorbed in our task. Irrelevancies will obtrude themselves. We perpetually find ourselves thinking of personal matters, directing our attention to bodily sensations or objects in the room, glancing out of the window, remembering items of purely local interest which we may have noticed in the daily press, forming plans for employing ourselves in the non-working part of the day. These irrelevancies may, from another point of view, be supremely important, but they are certainly irrelevant to the particular task before us. They obtrude themselves upon us because of the accident of our position in time and space. No doubt we shall be able to discover a certain unity in all the objects of which the self is aware throughout a tract of time and we might find full and complete system if we were omniscient.\* But, fortunately or unfortunately, we are not: and, therefore, when we give an impartial estimate of the actual unity of cognition and its objects which we find in experience we must admit that the unity of particular cognitive processes within the whole is greater than that of the whole itself.†

The point is very obvious but, perhaps, some further illustrations are not out of place. Let us consider the thoughts of a man who is a barrister and also a member of Parliament. As he masters each particular case his thoughts will have a close unity so far as they refer to this case. But when one case is over he will immediately set to work on another one which may be completely different. His legal knowledge and his legal methods will have a certain general unity but a much looser one than the unity of these particular cases. Then there are his thoughts about party and its principles (if there are any) and

its tactics. His habits of thought on legal matters will, no doubt, affect his political opinions. But the difference may be more marked than the resemblance. He will suit his speeches to the needs and the capacity of his audience, his views on particular questions will, probably, be much clearer and more definite than his grasp of general political theory. Moreover, the barrister will also have to think of personal matters—his business and his family.\* Speaking generally, then, his thoughts will refer almost contemporaneously to a number of different sets of objects. There will be a close unity of thought according as it refers to each particular set, but the unity is much looser when we consider the whole object of his various acts of cognition.<sup>1</sup> Similar arguments hold of the man of science and, *a fortiori*, of the thoughts of less distinguished people. We hear weekly from the pulpit, or could if we chose, that it is very dangerous to keep our religion for Sundays, our recreation for Saturdays, and our business for the other days of the week; but the preacher is really calling attention to a fact of psychology which is not peculiar to religion. Most men think consistently enough upon particular topics, but their thoughts, as a whole, are extremely inconsistent. They accept arguments on some occasions, which they would not tolerate on any others, and they could not explain consistently why they estimate the evidence so differently in different cases.

Hitherto we have tried to describe the unity of the cognitive self as it appears at a developed level. It remains, however, to formulate an account of cognition which will hold of the self at any stage of its career. We have to remember childhood as well as maturity, and second childhood as well as either. And it may appear that to say that knowledge, *e.g.*, requires recognition or that the object of perception must be seen to be continuous with the object of

previous perception, clearly implies the neglect of the first stage of knowledge or perception. But such speculations as to origin cannot be more than mere speculations. Even ambiguous evidence is lacking. Until we have unity and continuity of the type described we have something less than a self. It is probable that something which may perhaps be called experience preceded the type of experience which we know. But development, while it implies continuity, does not imply that the later stages are contained in the earlier. We might as well argue that the knowledge of the law of gravitation was contained in protoplasm. And therefore it is useless to attempt to explain developed cognition in terms of anything simpler. Nor have we any instance of, so to speak, a primordial thought which owes nothing to previous experience, and if the experience of a self is preceded by a type of experience below the level of selfhood then there is no need for seeking such a primordial cognitive act. This mode of argument, it may be objected, only serves to put the problem one stage further back; it does not solve it. Be it so. In that case I can only say that I do not dare to speculate on origins.

If we wish some general descriptive formula for this cognitive unity of the mind, it is best to say that the cognitive process is essentially logical. That may very well appear to be a definition *per obscurius*. A satisfactory definition of logic is not easily discovered, and the chief characteristic of many minds would seem to be their lack of logic. Common sense abounds in fallacies and is wont to leap to conclusions for which it cannot assign adequate grounds. We may talk if we will of intuition or super-logic, but this, when it occurs, is almost a happy accident, and is frequently only a flattering unction to confused thinking. Moreover, it is clear on any theory that concrete knowledge, whether of science or

metaphysics or common sense, involves more than formal logic. At the same time there is some meaning in the old formula that the essence of man is his rationality, the logical character of his thought. If he is not logical he apes logic. His very fallacies clothe themselves in the guise of logic. Only a mind acquainted with logic could commit logical fallacies. Moreover, most fallacies are fallacies of confusion. It is a fallacy to convert an A proposition simply. But many A propositions admit validly of simple conversion, and the fallacy, when it occurs, consists in hurriedly mistaking the one type of A proposition for the other. The disease is not usually incurable, for the mind which commits the fallacy can usually recognise the fallacy when it is pointed out. And in cases of so-called super-logic it is probable that steps of argument are vaguely apprehended and interposed. There is some tincture of a logical scheme despite the super-logic. And if, as philosophers, we deplore the vagueness and inconsistency of common sense the chances are that we are too pessimistic. Common sense is a kind of thinking. The philosopher must reckon with it. He cannot ignore it. He ought to recognise that common sense has usually grounds for its opinions and that these grounds are very likely to be correct. Its principal failing is that it is incompetent to express its grounds clearly and fully; and the philosopher should attempt first of all to elicit these grounds, following the example of Socrates in the *Meno*.

To say that the unity of cognition is logical need not mean very much, but at least it is an attempt to specify with an approach to accuracy. This logic, of course, is not the logic of the schools, although it includes that logic. The problems discussed in the logic of the schools are usually introduced from historical considerations and not because of some general unity of plan; and consequently school logic

is too often an amorphous collection of discussions on loosely connected topics. None the less, there is no real need for decrying its utility. The syllogism is not effete, and it is not a superstition, and immediate inferences really are inferences. Similarly the doctrines of definition, division, induction and the like, really deserve study. What is lacking is unity of plan and width of scope. Modern logic, and especially the labours of the mathematicians, have done something to unravel the tangle; but much remains to be done. And formal logic, however essential, is only the form and not the body of logical thinking. In its essence logical thinking consists in judgments of relevant connection, and the ordering of the results of these in connected series. It is in this sense, and in this sense only, that I wish to maintain that cognition is essentially logical, and I have done so despite the misconceptions to which the statement is liable.

A word may be said upon the place of intuition. The phrase intuition, especially 'intellectual intuition,' may have many meanings, as any one may see who cares to study the great period of German philosophy. But the most usual and the most important sense of the word intuition is that after a long and painful process of analytic investigation we may be able to *perceive* at a glance the whole setting and the whole truth of the facts before us. There is no piecing together bit by bit, there is no elaborate recognition of particular implications. The process is swallowed up in its result. The result is complete vision, complete insight, like the picture of his whole life which, we are told, flashes before the mind of a drowning man. Such vision is real although, of course, it is rare and sometimes fallacious; but, on the other hand, it does not dispense with logic. Let us suppose, for instance, that a new unifying hypothesis flashes upon the mind of a Darwin, or a Faraday. Then the

seer is able to perceive at a glance that this conception will apply to a multitude of instances. But his next task is to apply it in detail, and in that case the insight of intuition is only the beginning, not the end. And if it be replied that he still has the vision, and has it fuller and clearer, *after* he has applied his conceptions to detail, still it does not follow that the intuition has any higher validity than the applications. The intuition is only a general sense of the way in which a principle can be applied, together with a knowledge of the truth of the application in individual instances and an insistent psychological tendency to apply it in this way. It is as much a sense of power as a knowledge of truth. And it is no exception to our general theory

These remarks may suffice for a general description of the unity and continuity of the cognitive self, but before proceeding further it is advisable to add some explanations with reference to the kind of continuity implied. Just as the unity of the cognitive self as a whole is looser than that of particular series of cognitive processes within it, so in the case of continuity. With most of us the trend of our thoughts continues relatively constant for some time, and then diverges in a new direction. We begin a piece of work and after a time, willingly or unwillingly, the inevitable interruption comes and we direct our attention to something entirely different. We think of bridge instead of philosophy, and even in the most continuous and concentrated trains of thought there are repeated gaps in which we find ourselves thinking of something irrelevant. The important point is that temporal gaps are irrelevant to the continuity of thought. A long interval, no doubt, will somewhat impair that continuity, since it will imply some obliviscence, and the results of psychological experiments on memory seem to show that any interval has some slight effect of this kind. But

the continuity is much the most important feature of the case. When, next morning, we resume our philosophical studies after an evening of bridge, we take them up again at the point where we left them. The continuity of thought mocks at intervals of time, and this implies the noteworthy conclusion which we have already had occasion to mention.<sup>4</sup> If we consider all the objects of our thought throughout our lives or any portion of them we shall find a certain continuity, although comparatively little. On the other hand, we shall find very great continuity in certain trains of thought which occur intermittently in the course of our lives.<sup>5</sup>

It may be objected, however, that the continuity of these relatively disconnected trains of thought is more important from the point of view of personality than the more systematic continuity of the connected ones. In so far as the thoughts of two investigators are directed logically and systematically to the same problem the two thinkers agree. We see that they are really different persons when we notice their idiosyncrasies and the way in which the rest of their lives affects this portion of their thinking. Let us suppose, for instance, that the two investigators in question are philosophers or psychologists. Their arguments may reveal their personality only in comparatively irrelevant and accidental respects. We shall find what manner of men they are principally from the examples and illustrations they choose. The psychologist who is fond of billiards or of chess will be almost certain to mention one or other of these games in the course of his writings. Plato's philosophy stands for all time, but his examples are a mirror of the life of Greece. Argument of this type, however, rests upon confusion. The things in which men differ are not necessarily a more faithful index of their personality than the things in which they agree. On the contrary, in the instance before

us, the fact that both our investigators are psychologists or philosophers is probably the most distinctive feature of their personality. The influence of their studies upon the rest of their thinking is, probably, much more pronounced than the converse influence of the rest of their thinking upon their studies. There is much that is arbitrary in the way in which we say that the real man appears most distinctively in some one of the things which he does. Was the real Napoleon more manifest on the battlefield of Marengo or in the retreat from Moscow, at St. Helena or in the negotiations for the divorce from Josephine? The cognitive self, of course, includes all its cognitions, but that is no reason for maintaining that the general unity of these cognitions is the only feature of the self that requires mention. Nor is scientific or logical thinking really impersonal. It is always personal, but two thinkers may have the same kind of thoughts.

In passing to the unity of the self in feeling we should remember that this aspect of the self has been emphasised in general literature from a very early period. Since the times of Hippocrates and of Galen it has been usual to distinguish personality according to temperament. The division is rough and general like all others, but it is useful none the less. The choleric, the sanguine, the phlegmatic and the melancholic are always with us, and form distinctive types. It is true that the ancient division into temperaments and humours was based on physiology rather than on psychology, and did not refer to feeling only.

It may, by metaphor, apply itself  
 Unto the general disposition :  
 As when some one peculiar quality  
 Doth so possess a man that it doth draw  
 All his affects, his spirits, and his powers  
 In their confuſions, all to run one way.  
 This may be truly said to be a humour.<sup>1</sup>

---

<sup>1</sup> Ben Jonson, *Every Man out of his Humour*, Prologue

The affects, spirits and powers (or, in other words, feeling, knowledge, and will) all go to the making of a humour, or general disposition. But the reference is primarily to the affects or emotions, and these, we have said, are feelings. It is to the feelings of men that the satirist chiefly devotes his attention.

Quicquid agunt homines, votum, timor, ira, voluptas,  
Gaudia discursus, nostri farrago libelli.<sup>1</sup>

And the satirist is a master in psychology.

Again, the unity and continuity of feeling, and its connection with personality as a whole, was a prominent feature of early discussions of psychology. Spinoza was as great a psychologist as philosopher, and his analysis of the *affectus* or emotions in the third part of the *Ethics* bears this point constantly in mind. For him love and hate, joy and sadness, envy and pity are part of the setting of psychical life. They are, or imply, confused ideas, they determine thought, they are linked with the primary *conatus* which is our being. And in quite recent times we find in the theory of the sentiments, as it is presented by Mr. Shand<sup>2</sup> and others, a powerful commentary on the continuity of feeling. Indeed, a discussion of this doctrine is enough to raise the salient questions at issue.

Feeling, or the affective side of consciousness, includes, as we have seen, all kinds of excitement, all emotions, desire, pleasure and pain. But these feelings do not occur at random. They, too, are organised, and form a system, and the system centres round objects, or groups of objects. This fact is at once a proof of the unity and continuity of feeling, a confirmation of the view that feelings are references to objects, and an indication of the close connection between feeling and the other elements of consciousness. Hence its importance in the present place.

<sup>1</sup> Juvenal, *Sat.* i 85-86

<sup>2</sup> See his chapters in Stout's *Groundwork of Psychology*, and cf. Ribot, *La Psychologie des sentiments*.

We can trace the sentiments at every stage of psychical life. Although the child is not aware of the nature of the relationship between his mother and himself, he loves his mother, and she becomes the centre, to him, of a very complex world of feelings. He is pained at her absence, pleased with her presence. His hopes and his fears revolve round her. He admires her with all the strength of his little being. He is convinced that she is the best of all possible mothers, and, even in later life, his feelings with regard to a multitude of important questions are determined by his early association with her. He may disbelieve much that he has learned at her knee. He may consider her opinions speculatively unsound, but he will *feel* a strong respect for these opinions because of their connection with her. And, as time rolls on, a few faded lines in her handwriting, an old portrait, an old sketch will arouse a long train of reverie which is more than half feeling. This is true of all our feelings. They are centred round objects, they differ according to the circumstances of those objects, they become increasingly complex as our knowledge of those objects grows. When David lamented the death of Jonathan he showed what this unity of feeling is. He was proud of what Jonathan had been, he felt sorrow for his death and for the emptiness which that had brought to his own life, and withal he felt joy in the memory of their companionship and pleasure in the thought of what each had been to the other. And if we try to analyse our feelings towards our old home, or our country, our pride in them, our fears for them, our love of them, we find another illustration of this same truth. We feel with our world, our feelings grow with that world and refer to it.

It follows that there is the closest possible connection between the unity of feeling and the unity of cognition. One or the other may predominate in

certain persons, but the unity of the two is much more important than the predominance of either. The failure to recognise this fact has, I think, had a very unfortunate effect on much modern discussion of social psychology. The reaction against the psychology of the earlier English economists has all the marks of an extreme reaction. Feeling is enthroned and reason displaced for reasons which are specious but inadequate. One wonders at the title of feeling to the throne, and it may not be amiss to consider it.

We may admit that the psychology of these early economists was seriously defective. In affairs political men do not act and vote merely according to reason, even if that 'reason' be enlightened self-interest. And the general education of the masses has not appreciably increased the intellectual value of a vote. So much must be admitted, but it does not follow that blind impulse and emotion have the reins of power. Let us grant that rhetoric is more potent than argument; and posters, emblems and catchwords more important than either. The picture of the little loaf is still, perhaps, the best argument for free trade. But such posters are not merely appeals to feeling. They are appeals to perception and what it suggests. This is less than reason, it is true, but it is not entirely irrational, and it is not an appeal to blind feeling. So far as it is an appeal to feeling, it is really an appeal to the sentiments aroused by this perception. Only a rational being could have these sentiments, and only to him would the poster suggest a meaning. What is necessary is to stimulate the imagination of a voter, and his imagination is not entirely irrational. The poster simulates logic, the catchword pretends to be argument, and if the pretence is better than the reality, the mere fact that it is a pretence is surely of great significance.

There is no question of a *de facto* deposition of

reason. True, our emotions often carry us away, and disturb the clear current of thought. But they do so, not by obliterating all the evidence, but by suppressing part of it. Instead of considering the British public during the fever of an election, let us consider its members when their blood is cooler and they are reflective. Then reason enters, and it does not stand apart without any influence on the subsequent current of their thoughts and actions. The broader view which they take may seem to cease at the next election, and may be prompted by nothing better than selfish dissatisfaction with the government for which, not long before, they shouted *Io Trumphe!* But even so, there is a distinct influence of reason. What is the meaning of it all? Feeling prompts to the act of noticing principles as well as to other acts. Therefore the sentiment guided by a certain interpretation will prompt to a fuller appreciation of that interpretation, and will temporarily obscure any other point of view. This is the result of the poster, or the catchword, and of the sentiments they arouse. But dissatisfaction resulting from fuller knowledge will prompt the embracing of the contrary. It is far from certain that two different men can ever feel differently with regard to the same question. If we include in the question all the meaning it suggests to each of them, there will probably be a different question for each. The principle seen after the election will seem different from that which is seen during the election.

We might even say that there is a logic of the sentiments. Whether that be so or not there is unity in feeling, and enlightenment in feeling. But the perception of this truth must not drive us into error. We must not exaggerate the degree of system in the feelings any more than in the cognitions of the self. The sentiments of the child, for instance, are loosely organised, just as his knowledge is loosely organised, and there is none of us in whom the

sentiments, any more than the system of knowledge, form a perfect whole, *totus, teres, atque rotundus*. Our sentiments are as inconsistent as our judgments. Of two rebellions which are really *in pari materia*, we applaud one and loathe the other; but we shall also find that the two are *understood* differently. We understand the causes of the rebellion which we applaud, and enter into the motives of the rebels. We know that this rebellion is not merely a case of wicked perversity. The same is probably true of the rebellion we detest, but in that case all we know is the ugly fact that there is a rebellion. We have no inner knowledge of the forces at work, many of which may be intrinsically valuable. Part of the reason for the difference of sentiment may be the wilful neglect of some aspects of the object we admire as a whole. We can justify the end only by shutting our eyes to the means. But the main reason is the fulness and intimacy of our knowledge of circumstances. The difference in the emotions of two men with regard to socialism depends chiefly on how they understand socialism. To the one it is an abhorred fury, working havoc with morals, religion and the family. To the other it is a panacea for the rottenness which pervades the core of society. And the unity of feeling is built up around these divergent interpretations. We must not overrate the unity of cognition; we must not underrate the unity of feeling. *De gustibus non est disputandum*. It may be so; but remember the correlative maxim, *Quot homines, tot sententiae*.

The unity and continuity of endeavour, as we have seen, is the basis of one of the principal arguments for the primacy of will. To strive persistently for an end, with various modifications as circumstances dictate, is a fundamental characteristic of the self. We find ourselves in the fulfilment of our aims. We inhibit warring tendencies, and neglect the unessential, and so we come to seek and understand, to

a greater or lesser degree, the end and aim of our being. In a way we narrow our energies because we restrict them. This is the difference between the day-dreams of youth, with their unlimited outlook on possibilities, and the sober, narrow earnest of the man of affairs. But in another way we expand our energies in and through this very concentration, and, on the whole, expand them consistently. • Sedulous attention to details is the only activity worth pursuing.

Indeed it is more important to notice the limitations in the unity and continuity of endeavour. There is nothing easier than the overstatement of a general truth. To say that human beings persistently follow a single plan of life, even if that plan is known to them only in part, is clearly not a true description of fact. If we find our real aims in their partial fulfilment, we also modify these aims, in the majority of cases, beyond all recognition. If there is a real aim it is often real only because we are driven to it, and there is also a place for wanton caprice. The self develops and it also decays. Development, it is true, implies continuity of process, unity and differentiation in maturity, and novelty in the later stages as compared with the earlier, but it is impossible to specify the degree of unity and continuity which is requisite for the existence of development in any given instance. The fact of novelty does not destroy identity, but it certainly destroys many hasty interpretations of identity. Samuel Butler says somewhere that 'life is like a fugue. Everything must grow out of the subject and there must be nothing new.' Perhaps it is so. But in what sense does a fugue contain nothing new, and is not the unity of our plans a lesser thing than the harmony of a fugue? Moreover, when disintegration always accompanies progress, and senescence is wedded to growth, does it not seem that discontinuity is just as important as unity or continuity?

As it is with our thoughts, so it is with our purposes. There is a closely knit connection in many particular strands of a life, and a much looser continuity in the fabric as a whole. The day's labour may be concentrated and organised, and perhaps the day's pleasures, severally and individually. We can explain what we are doing in each of these cases, and what we want to get. It is a far harder task to explain their unity as a whole. These several activities are connected *inter se*. If the telephone bell, with its message of business, calls a man from a rubber of bridge, he will switch his business mind on to the telephone with an accuracy that rivals the exchange, and weave the message into his business plans at the point where he left them off. And when he returns to the bridge table, he will switch off from business, and play to the score as it was left. But this is a question of separate unities connected together comparatively loosely. No doubt there is some connection, if it be only in the plans for the disposition of time, and some pursuits irradiate into others. 'Shop' has been heard on the golf links ere now, and a man's profession is sometimes stamped on his outward appearance. Again, in looking back on our lives as a whole, we can often detect very close resemblances between our purposes then and our purposes now. But let us beware of a very prevalent fallacy. Are we not inclined to call these purposes fundamental because the continuity in their case is very clear, and we like to appear consistent to ourselves? The kind and degree of the continuity of the self can never be discovered if each investigator marks only where he hits, and neglects the disunion and the caprice.

The conclusions of the argument in this chapter may be expressed very briefly. The claim to selfhood demands unity and continuity of a distinctive type, and it is essential to investigate the particular type of unity and continuity which appears at the

level of experiences. When the importance of the recognition of this unity has once been admitted, the danger of exaggerating it becomes very real, and this danger must be carefully avoided. On the other hand, there is a pronounced and important unity and continuity which appears equally, though diversely, in feeling, endeavour, and cognition respectively; and, despite the diversity, there is a manifest similarity in all these instances. There is a logic of the sentiments as well as a logic of cognition, and it is unnecessary to add that there is a logic of endeavour. The unity of endeavour, the persistent striving for an end with variations of detail, appears precisely in the measure in which there is a consistent plan. Such a description, however, must not be taken to imply that there is any primacy of cognition. If the unity of cognition has been discussed more fully in these pages than that of either feeling or will, the reason is only that there has been a tendency to neglect it in some recent discussions. The important point is the correspondence of the unity in all the features of mind. This correspondence in all the elements, together with the co-ordinate importance of each, is a convincing proof of the reality of the unity.

I shall conclude this discussion by mentioning a very obvious corollary of its argument. The analysis of the unity and continuity of the self is also the analysis of personal identity, and therefore has been the subject of a great deal of philosophical discussion. Our argument has referred only to the identity of that self which can be discovered by introspection. This self, it is plain, consists of experiences, and its identity is of the experiences. We can recognise the identity in one way only, that is to say by a judgment of comparison. It is necessary to compare the self at some time in the past with the self as it is in the present, and then we can tell whether and in

what respects it is identical. Thus personal identity does not involve any peculiar logical difficulty. We must be identical if we can recognise our identity in judging. We require memory in order to make the comparison implied in any judgment of identity; but memory does not make us identical. It merely supplies part of the evidence for recognising the fact. We must remember the self of the past in order to compare it with the self of the present. Perhaps there is no personality which is incapable of recognising itself in this way, but that is another matter. And, of course, if we continue the same selves from year to year, there are long tracts of our existence which have disappeared from our memory except in the vaguest and most general way. But our identity must include these forgotten experiences. They were parts of us as truly as the experiences which we remember.

When we reflect on personal identity, however, we tend to think of objects as much as of experiences. Our thoughts go back to scenes we have witnessed, and events in which we have been partakers. The men we knew and the things we loved pass before us in review. Our identity is correlative to their existence, so far as we were connected with them. And, in particular, we are apt to regard bodily identity as part of what we mean by our own identity. As I have shown, the reasons for this lie very deep, deeper, even, than the fact that our evidence for the identity of other men must be drawn, principally, from the identity of their bodies. But it may seem that no amount of argument can be sufficient to overthrow this plain testimony of introspection. *Quod semper, quod ubique, quod ab omnibus*. There is a catholicity of experience which will brook no denial. The attempt to show that the unity and continuity of experiences is all that personal identity means to introspection is foredoomed to failure.

The objection seems convincing, but the reply is adequate. An experience is a reference to an object, its being is so to refer, it varies as the object varies, and to define it, or to think of it, without reference to its specific object is plainly impossible. Accordingly it is not an objection that we should think of objects when we think of our own identity. The unity of the world for us is an infallible criterion of the unity of our experiences. Our private experience shows itself in the things and events to which it refers. These things and events are not ourselves, though we would not be ourselves unless our experiences were directed to them. And, therefore, the facts are consistent with our argument.

By the same reasoning there is no paradox in the fact that personal identity should seem to be so much an affair of the body, or that abrupt changes in organic sensation should lead us to doubt whether we are the same. Our organic sensations, and our body on any interpretation, form a background which is constantly present with us. They must be present with us as part of the total complex to which our experiences are directed at any given time. And no other thing is constantly present in the same way. What wonder, then, that we should always think of our bodies when we think of ourselves? The object of introspection is an experience, or complex of experiences, referring to some object; and we cannot think of our experiences without thinking of their objects. A constant object, therefore, must always be thought of, when we think of ourselves. We carry this body and these organic sensations about with us wherever we are, on land or sea, in the prairie or the city. True, their constancy is only approximate. They differ profoundly in the heat of the Sahara and in the Canadian winter. They differ with most of us on land and on the sea. But if their constancy is relative, so is our constancy. They are always with

us, despite their variations. They are more constant than our clothing or our immediate environment, and these, sometimes, seem part of our being. It would be idle to expect general agreement on so complicated a topic as this. But if the body is never part of the self, and I have tried to show that it is not, it is at least possible to show why we should tend to regard it in that light.
